

# Physical properties of high-entropy alloys

Janez Dolinšek

Institut "Jožef Stefan", Ljubljana, Slovenija

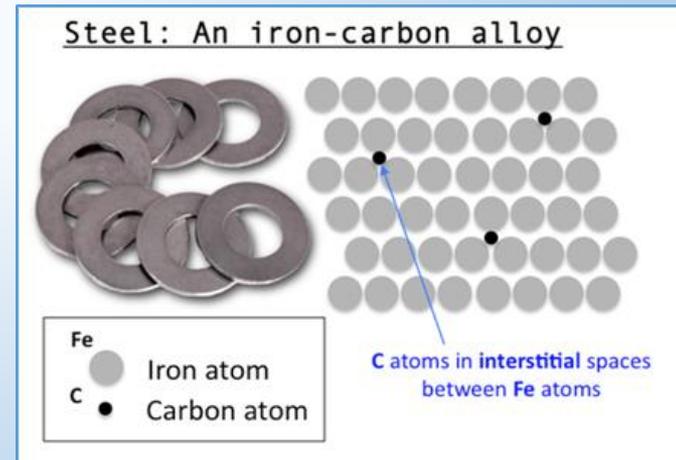

University of Ljubljana

Faculty of Mathematics and Physics

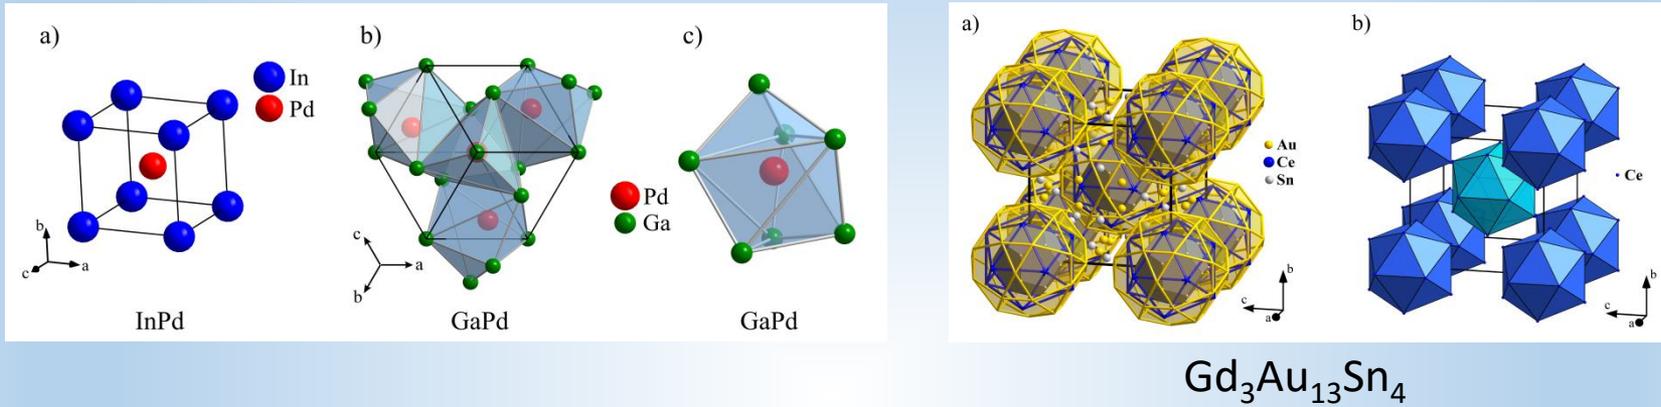

# Traditional metallic alloy systems

- based on one principal chemical element as the matrix,
- other elements incorporated in small amounts for property/processing enhancement,
- about 30 practical alloy systems developed (Fe (steels), Al, Cu, Ti, Mg, Ni-based).

# Alloys with more than one principal element

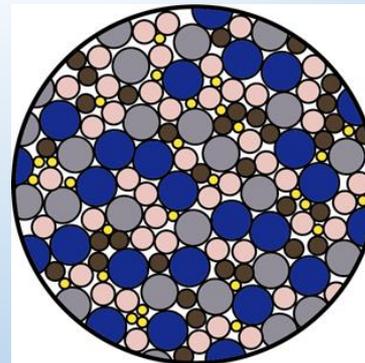

## Intermetallic compounds (structurally simple or complex - CMAs)

## Bulk amorphous alloys (metallic glasses, Pd, Ln, Zr, Fe, Mg-based)

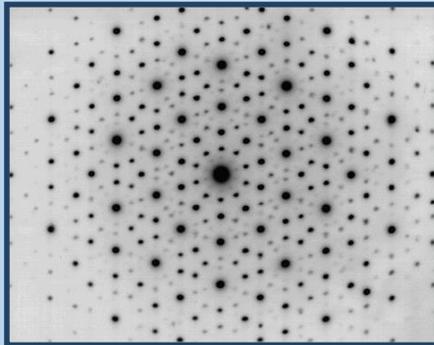

Zr<sub>69.5</sub>Cu<sub>12</sub>Ni<sub>11</sub>Al<sub>7.5</sub> XRD pattern

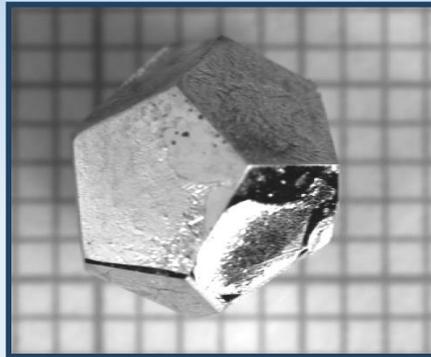

# Alloys with more than one principal element

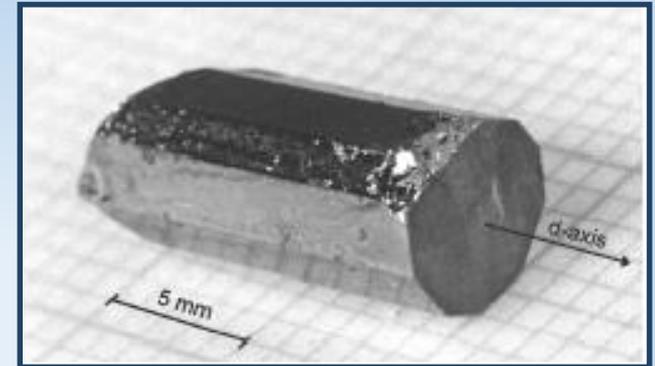

## Quasicrystals

diffraction pattern

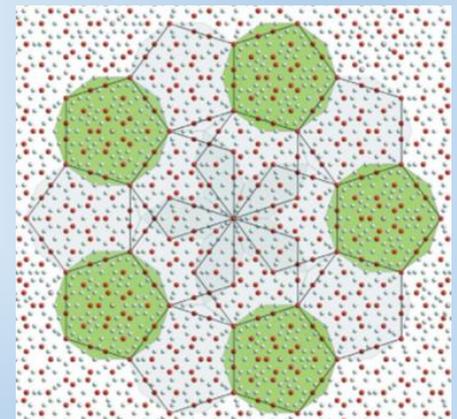

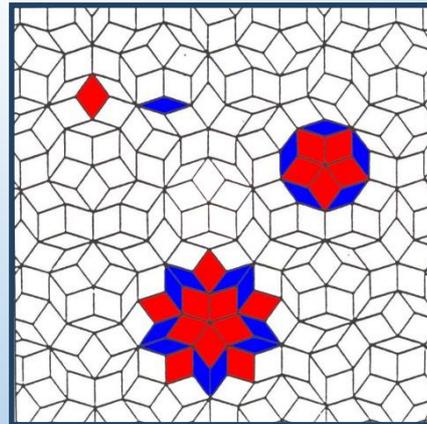

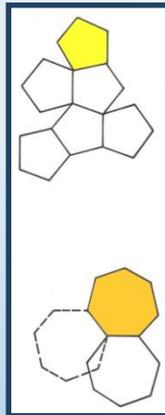

icosahedral Mg-Zn-Dy

decagonal Al-Ni-Co

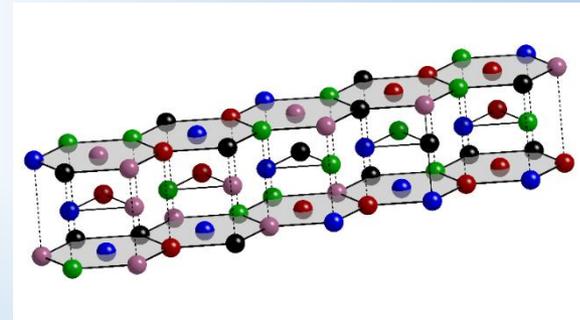

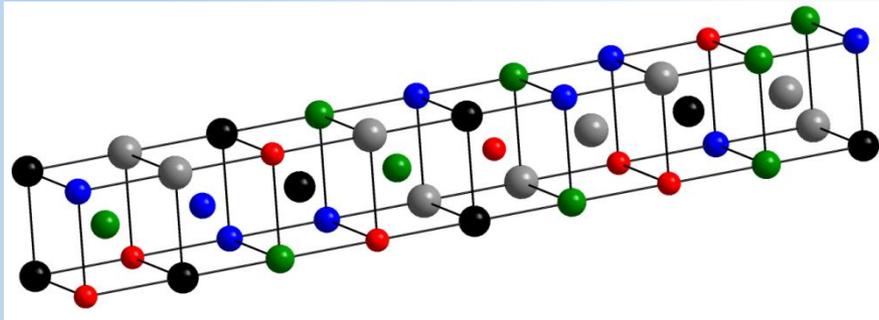

“forbidden” symmetries: 5-, 8-,  
10-, 12-fold axes

Shechtman *et al.*, Phys. Rev.  
Lett. 53, 1951 (1984)

# High-Entropy Alloys (HEAs)

- new concept of alloy design with multiple principal elements in near-equimolar ratios,
- high entropy of mixing can stabilize disordered solid-solution phases with simple structures (bcc, fcc, hcp) and small unit cells,
- topologically ordered lattice with exceedingly high chemical (substitutional) disorder.

**HEA: “*metallic glass on a simple, ordered lattice*”**

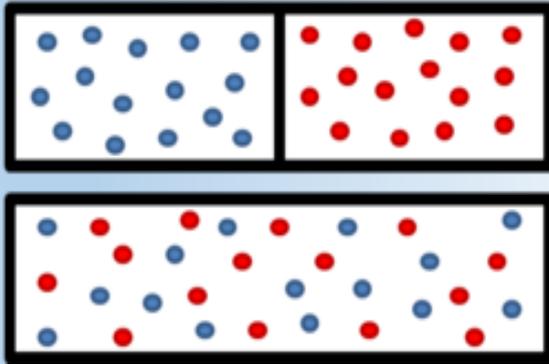

J.W. Yeh, *et al*, Adv. Eng. Matter. 6, 299 (2004),

J.W. Yeh, Ann. Chim. Sci. Mat. 31, 633 (2006).

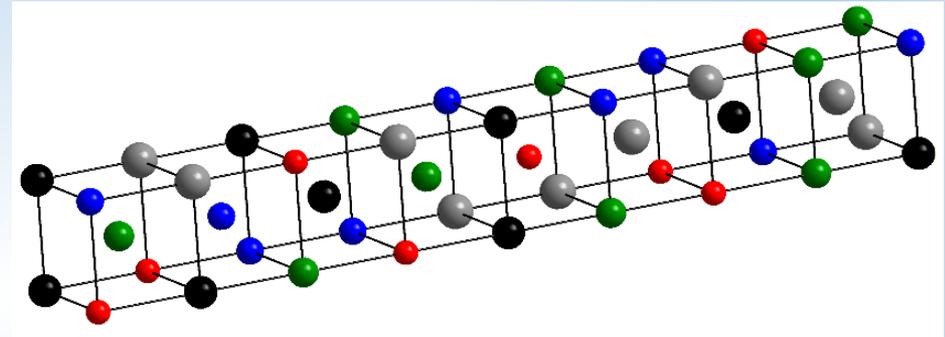

# High-Entropy Alloys (HEAs)

Conditions for the HEA-phase formation:

- high entropy of mixing should be achieved,

random mixing of ideal gasses

random mixing in a solid solution

- alloy must be composed of 5 or more majority elements in similar concentrations (from 5 to 35 at. % for each element),
- no element should exceed 50 at. % concentration.

# HEA phase stabilization

- minimization of Gibbs free energy  $G = H - TS$  by the entropic term

- mixing free energy:  $\Delta G_{mix} = \Delta H_{mix} - T\Delta S_{mix}$

- mixing (configurational) entropy of an  $r$ -element ideal gas (  $\Delta H_{mix} = 0$  ):

$$\Delta S_{mix} = -nR \sum_{i=1}^r x_i \ln x_i$$

$x_i = n_i/n$  ... molar fraction of component  $i$

- equimolar concentrations of elements:  $x_i = 1/r$

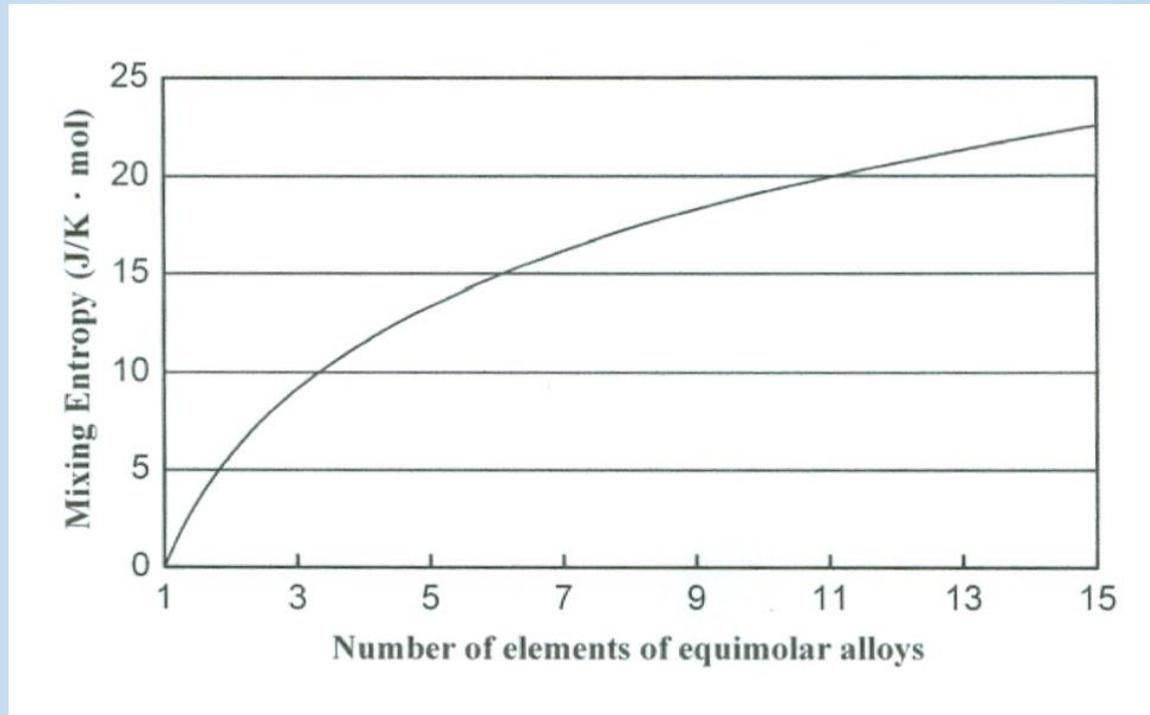

entropy of mixing reaches maximum

$$\Delta S_{mix} = nR \ln r$$

# HEA phase stabilization

mixing entropy versus the number of elements in equimolar alloys

J.-W. Yeh, *Annales De Chimie – Science des Materiaux* 31, 633 (2006)

# HEA phase stabilization - example

- five-component mixture ( $r = 5$ ) with equimolar ratios of the elements:

$$\Delta S_{mix} = R \ln 5 = 13.4 \text{ J / molK}$$

- high temperature, e.g.,  $T = 2000 \text{ K}$ :

$$T\Delta S_{mix} = 26.8 \text{ kJ / mol}$$

energy gain of a few 10 kJ/mol is enough for the entropic stabilization of a disordered solid-solution phase with a simple structure (bcc, fcc, hcp), in competition with ordered complex crystalline intermetallic phases

# HEA phase stability – ideal solid solutions

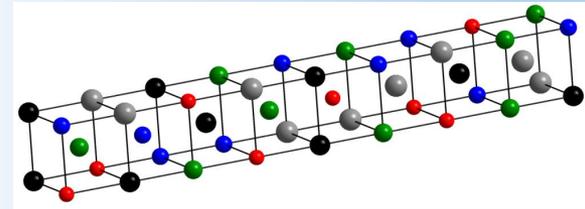

## Ideal solutions:

- interactions between every pair of molecular kinds are the same,

$$\Delta H_{\text{mix}} = 0$$

$$\Delta G_{\text{mix}} = -T\Delta S_{\text{mix}}$$

- mixing of the elements is completely random,

- solid solution with a simple structure is stabilized by the entropy term and is thermodynamically stable down to low temperatures.

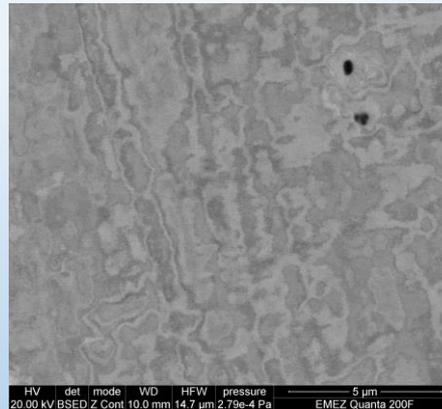

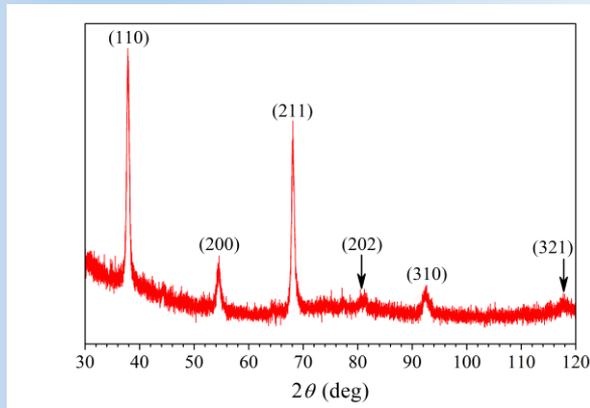

# HEA phase stability – regular solid solutions

- real solid solution ( $\Delta H_{\text{mix}} \neq 0$ ): interactions between different molecular kinds are different,
- low temperatures: the entropy term  $T\Delta S_{\text{mix}}$  becomes too small to stabilize a HEA phase,
- sluggish atomic diffusion in multi-component mixtures hinders phase transformations  
→ simple high- $T$  structure quenched down to low- $T$  (metastable),

$\Delta H_{\text{mix}} < 0$  : intermetallic phases precipitate at the nm scale,

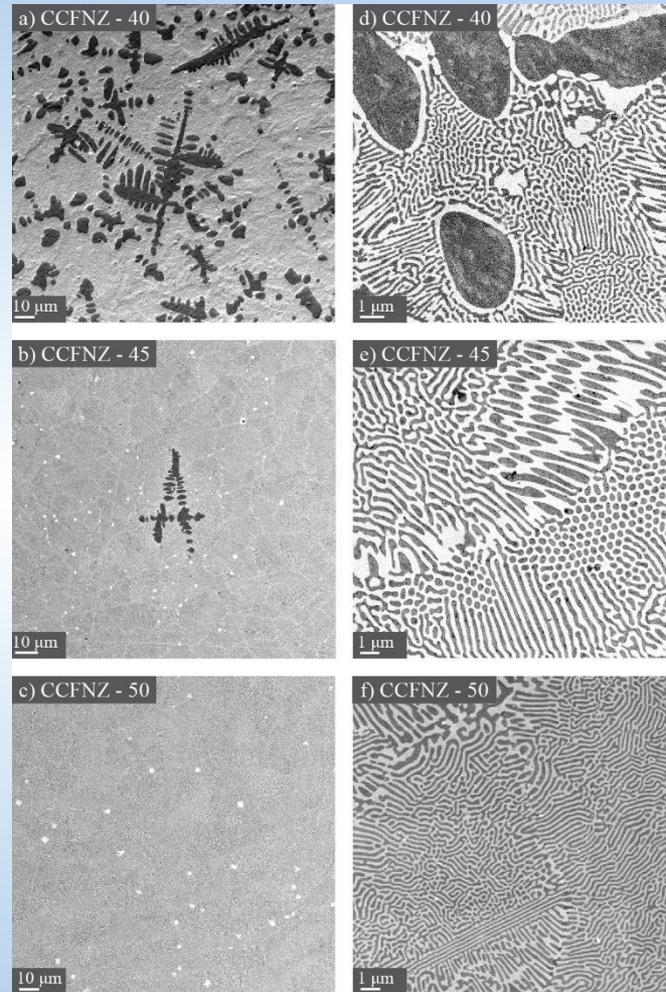

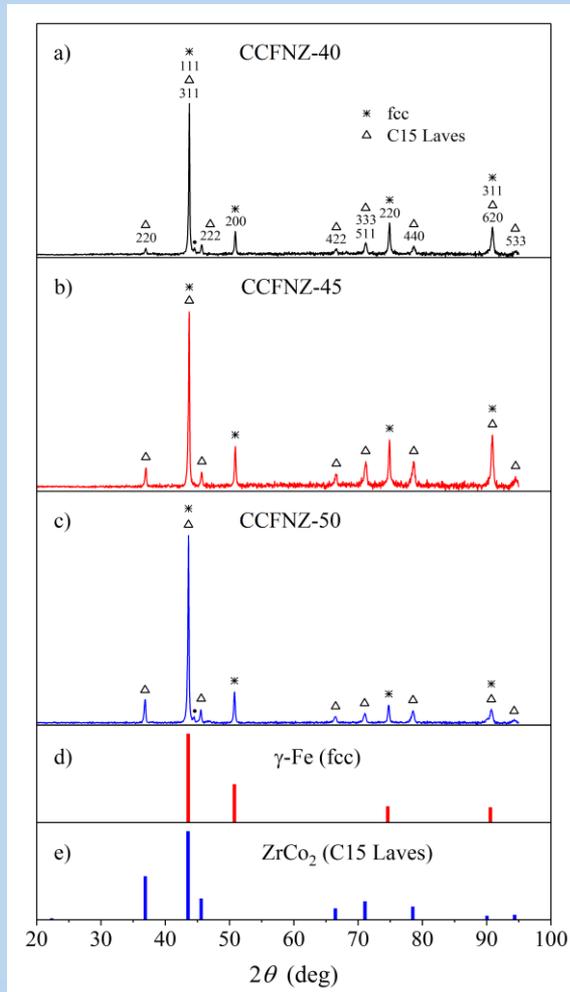

$\Delta H_{\text{mix}} > 0$  : phase separation (dendrites).

$\text{Ta}_{34}\text{Nb}_{33}\text{Hf}_8\text{Zr}_{14}\text{Ti}_{11}$  bcc HEA

SEM BSE image at the  $\mu\text{m}$  scale

# CoCrFeNiZr<sub>0.45</sub> bcc HEA - regular solid solution

# Examples of HEA systems

**bcc and fcc HEAs:**

**Ta-Nb-Hf-Zr-Ti-Nb-Mo-V-W**

**Al-Si-Co-Cr-Cu-Fe-Mn-Ni-Ti**

**hexagonal HEAs:**

**Gd-Tb-Ho-Dy-Er-Tm-Lu-Y**

- enhanced mechanical properties (high hardness, solid-solution strengthening)
- refractory materials (stable at high temperatures)
- superconductivity
- magnetic softness
- magnetic nanocomposites
- complex magnetic phase diagrams

# Superconductivity in the Ta-Nb-Zr-Hf-Ti system

## Ta-Nb-Zr-Hf-Ti:

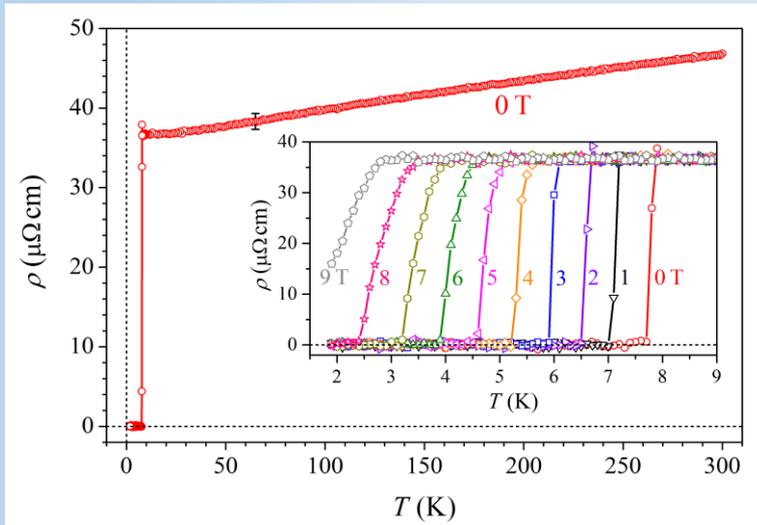

9 % atomic radius mismatch between the largest (Zr) and the smallest (Ti) element

## upper critical field

# Soft ferromagnetism in FeCoNiPdCu

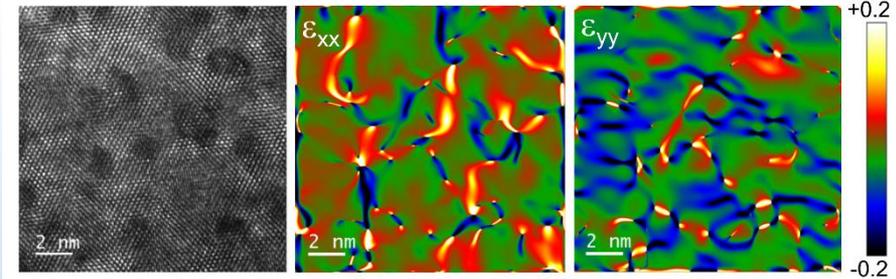

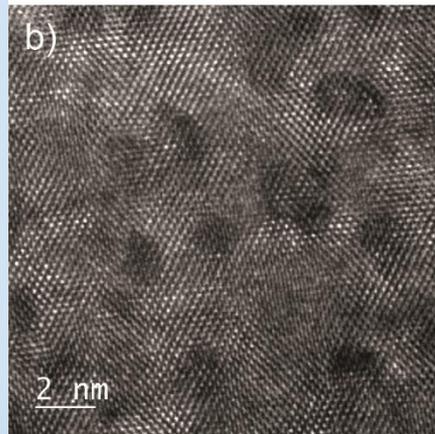

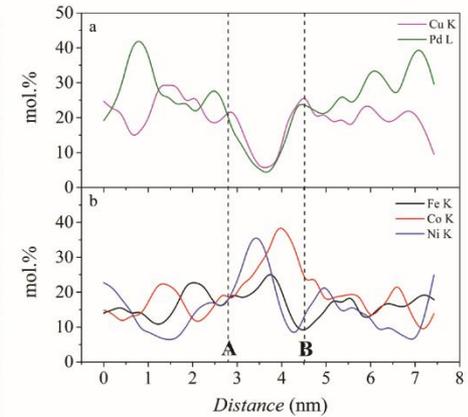

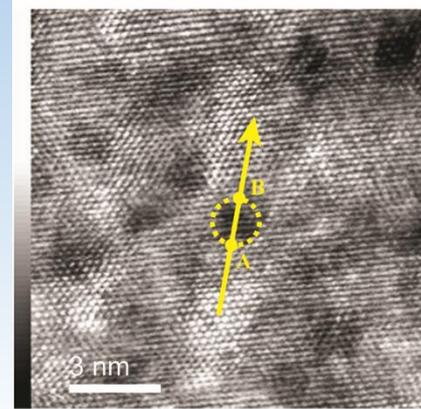

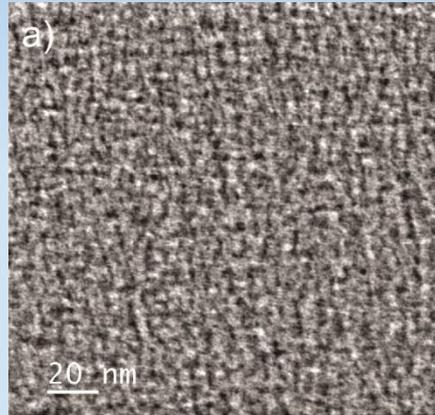

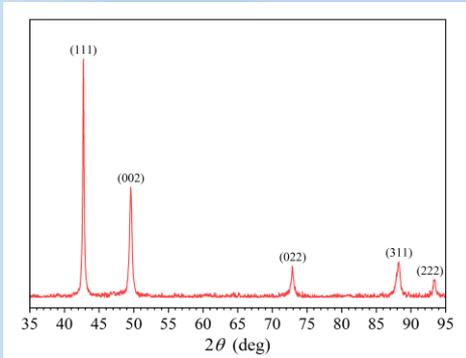

FCNPC: FeCoNiPdCu HEA

NES: non-oriented electrical steel ( $\text{Fe}_{97}\text{Si}_3$ )

Use in: transformers, electromotors, electromagnetic machinery, magnetocaloric refrigerators

# Soft ferromagnetism in FeCoNiPdCu

**Nanocomposite of FeCoNi  
ferromagnetic nanodomains  
and CuPd nonmagnetic  
„nano-spacers“**

**exchange averaging of  
magnetic anisotropy**

**perfect magnetic softness**

**P. Koželj et al., Adv. Eng. Mater. (2019) 1801055  
DOI: 10.1002/adem.201801055**

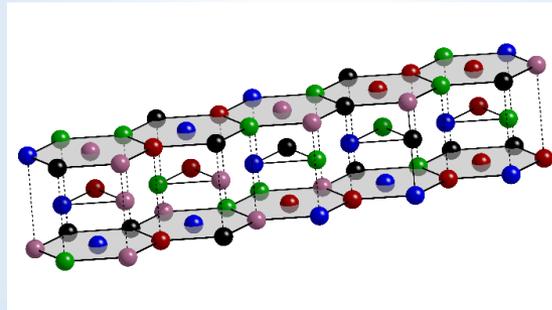

# Complex magnetism of rare-earth based hexagonal HEAs

- investigated system: **Ce-Gd-Tb-Dy-Ho-Er-Tm-Lu**

- binary mixing enthalpies of any pair of the elements are zero:

$$\Delta H_{mix}^{ij} = 0 \quad \Rightarrow \quad \Delta H_{mix} = 0 \quad \Rightarrow \quad \Delta G_{mix} = -T\Delta S_{mix}$$

- RE-based hexagonal HEAs are ideal solid solutions;

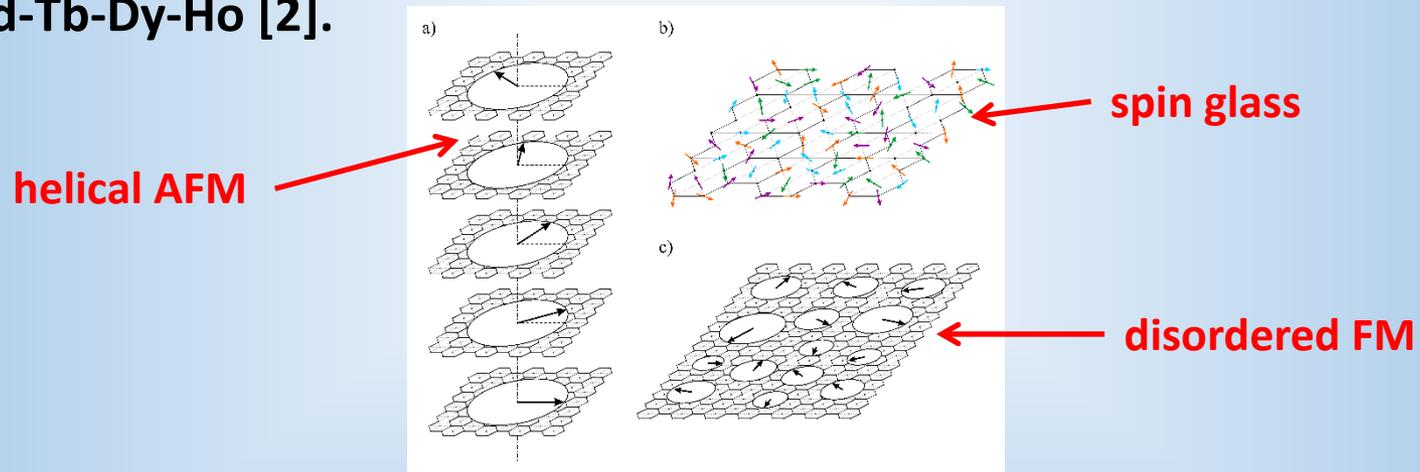

- atomic radii are very similar  $\Rightarrow$  lattice distortions small;

- large chemical disorder.

*„Metallic glass on a topologically ordered lattice“*

# Physical properties of RE-based hexagonal HEAs

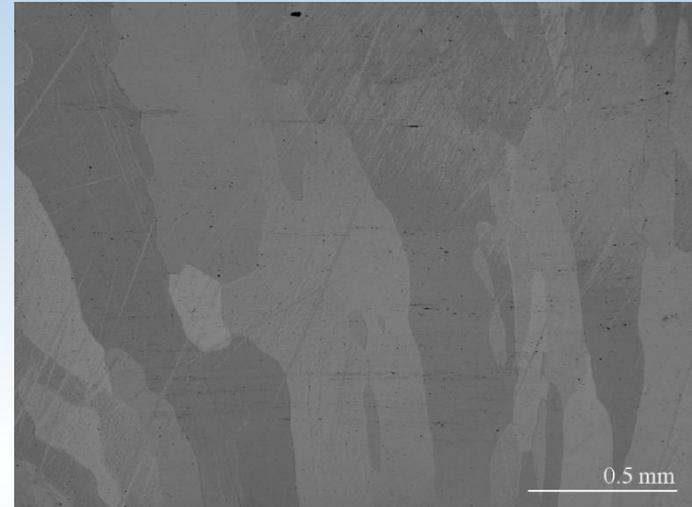

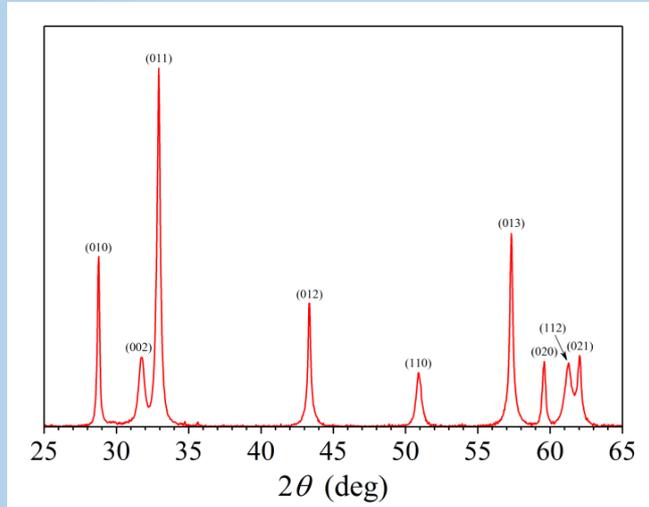

- Great chemical similarity of the RE elements  $\rightarrow$  electronic properties can be predictably tuned with composition;
- Random mixing of RE elements on an undistorted hcp lattice results in unprecedented magnetic behavior;
- Complex  $(H, T)$  phase diagrams observed in Y-Gd-Tb-Dy-Ho [1] and Ce-Gd-Tb-Dy-Ho [2].

[1] J. Lužnik, *et al.*, Phys. Rev. B 92 (2015) 224201.

[2] S. Vrtnik *et al.*, J. Alloys Compd. 742 (2018) 877.

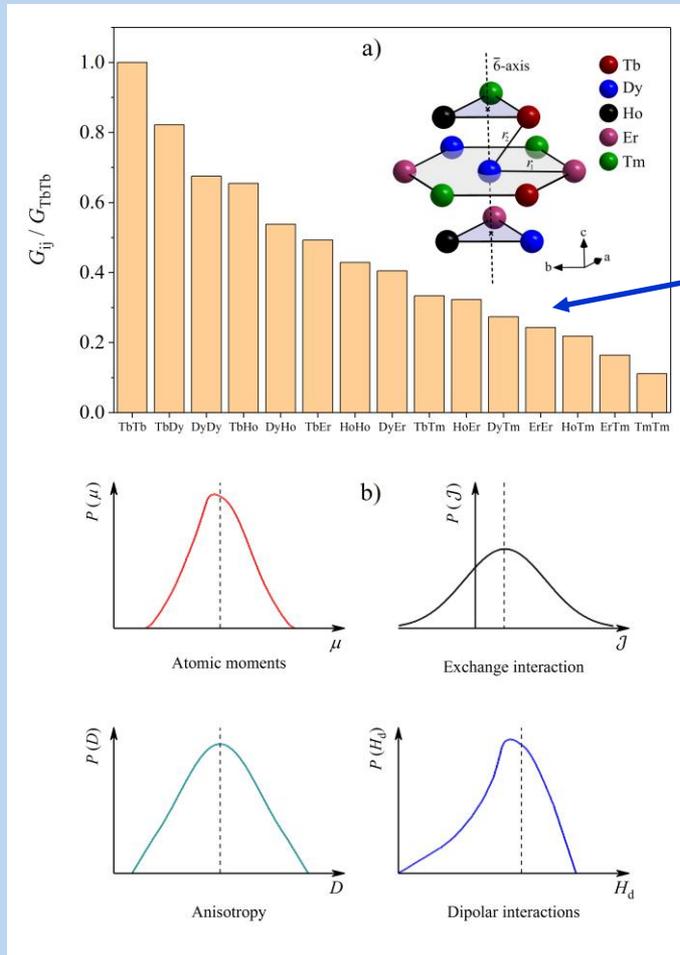

# Physical properties of Tb-Dy-Ho-Er-Tm hexagonal HEA

SEM BSE – channeling contrast

- single-phase material, macroscopically large grains;
- hcp structure, space group  $P6_3/mmc$ ;
- RT lattice parameters:  $a = 3.582 \text{ \AA}$  and  $c = 5.632 \text{ \AA}$ , in good agreement with the composition-averaged theoretical values  $\bar{a} = 3.575 \text{ \AA}$  and  $\bar{c} = 5.622 \text{ \AA}$ ;
- EDS composition:  $\text{Tb}_{20.3}\text{Dy}_{20.7}\text{Ho}_{20.3}\text{Er}_{19.7}\text{Tm}_{19.0}$

# Magnetic interactions in Tb-Dy-Ho-Er-Tm hexagonal HEA

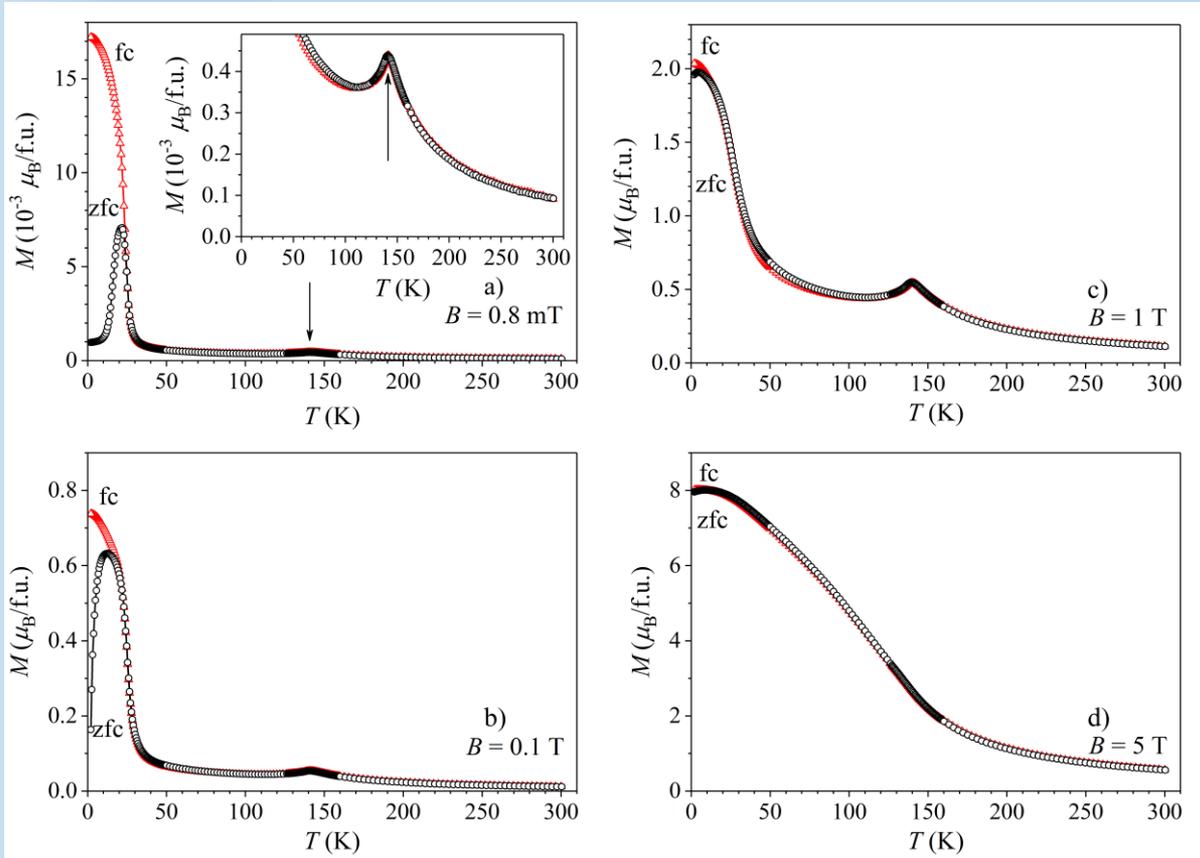

de Gennes factor (strength of the exchange interaction between different atomic pairs)

Probability distributions of:

- atomic magnetic moments  $P(\mu)$ ,
- exchange interactions  $P(\mathcal{J})$ ,
- magnetocrystalline anisotropy  $P(D)$ ,
- dipolar interactions  $P(H_d)$ .

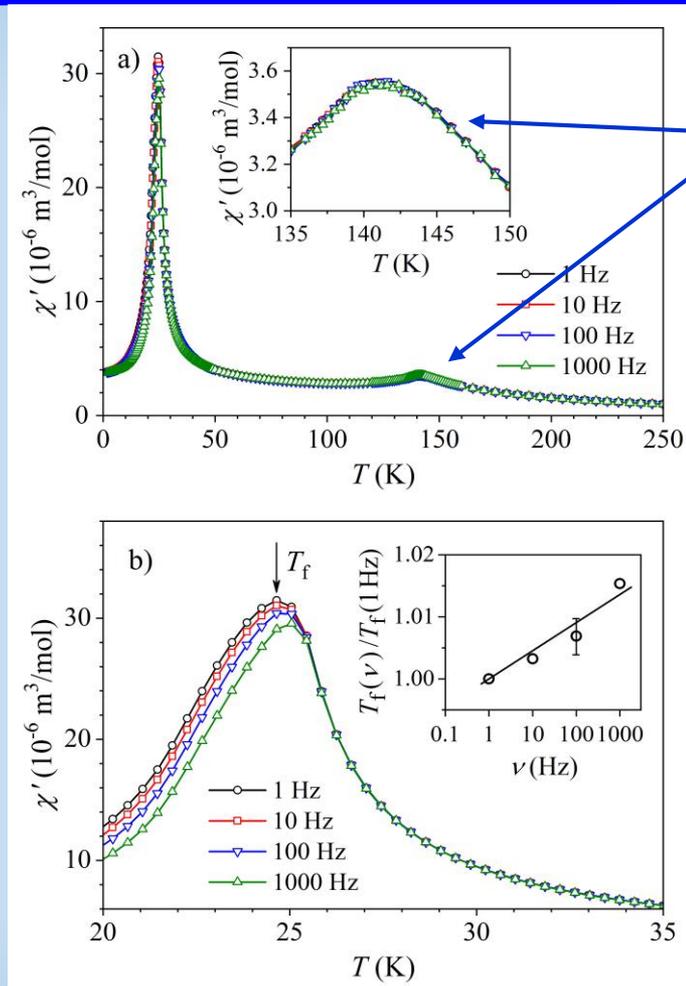

# dc magnetization of Tb-Dy-Ho-Er-Tm hexagonal HEA

two magnetic phase transitions:

- AFM-like at about 140 K
- FM-like at about 24 K

# ac magnetization of Tb-Dy-Ho-Er-Tm hexagonal HEA

transition at 140 K is frequency-independent:

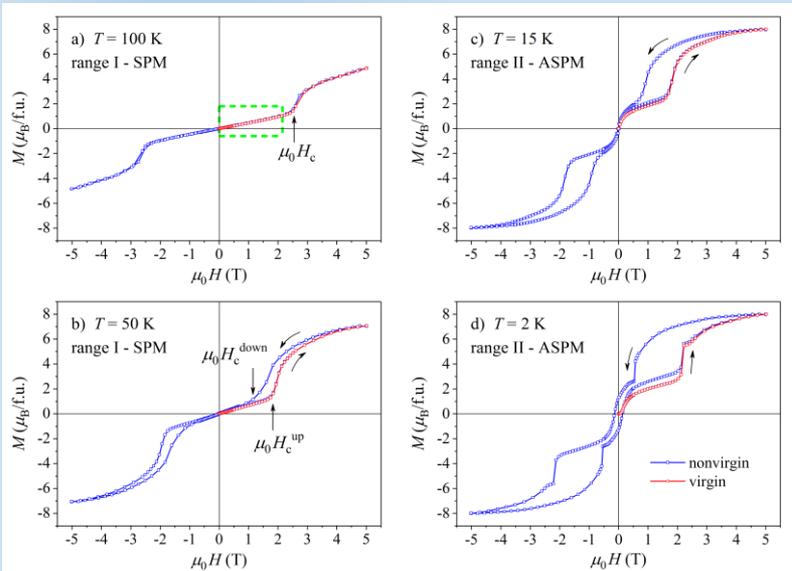

thermodynamic phase transition

transition at 24 K is frequency-dependent:

spin freezing transition in a magnetically frustrated system

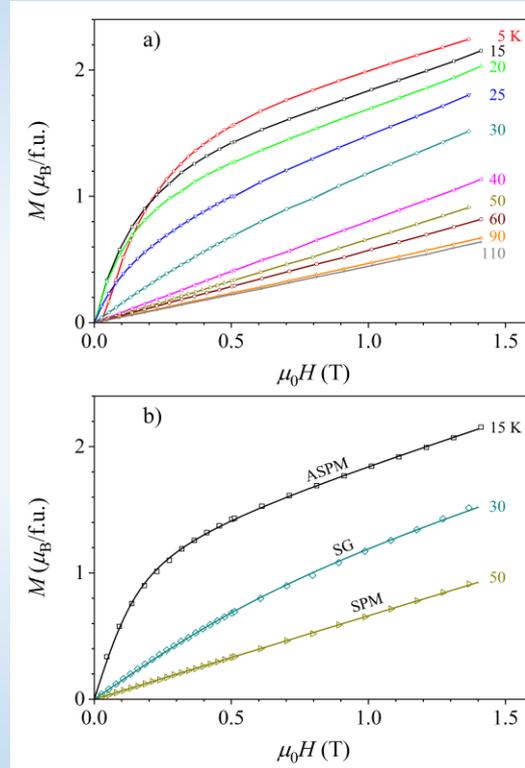

# M(H) curves of Tb-Dy-Ho-Er-Tm hexagonal HEA

M(H) dependence changes at a „critical“ field  $H_c$

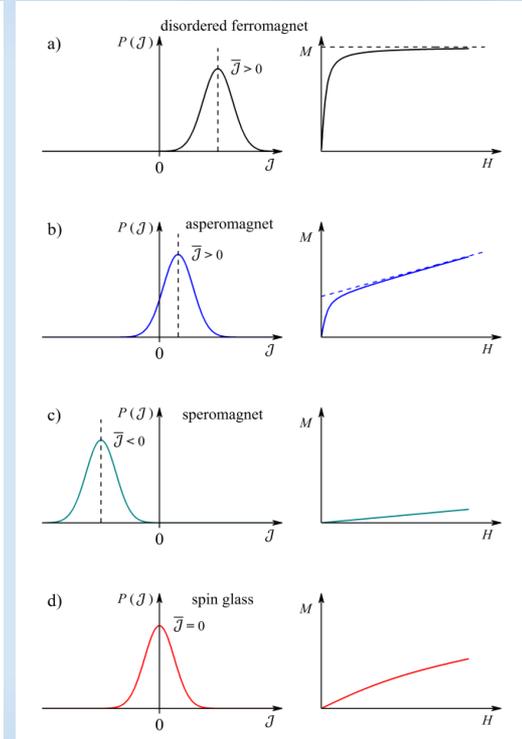

ASPM: asperomagnet  
 SPM: speromagnet  
 SG: spin glass

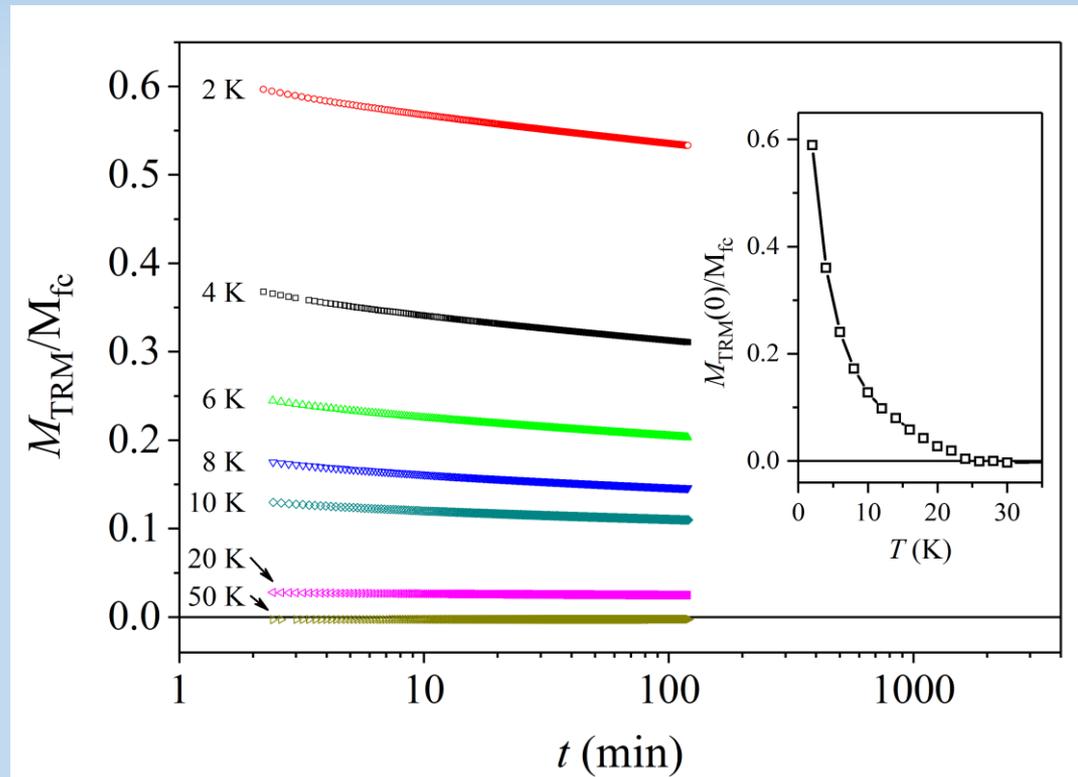

low-field M(H)

types of magnetic order

# Thermoremanent magnetization time-decay of Tb-Dy-Ho-Er-Tm hexagonal HEA

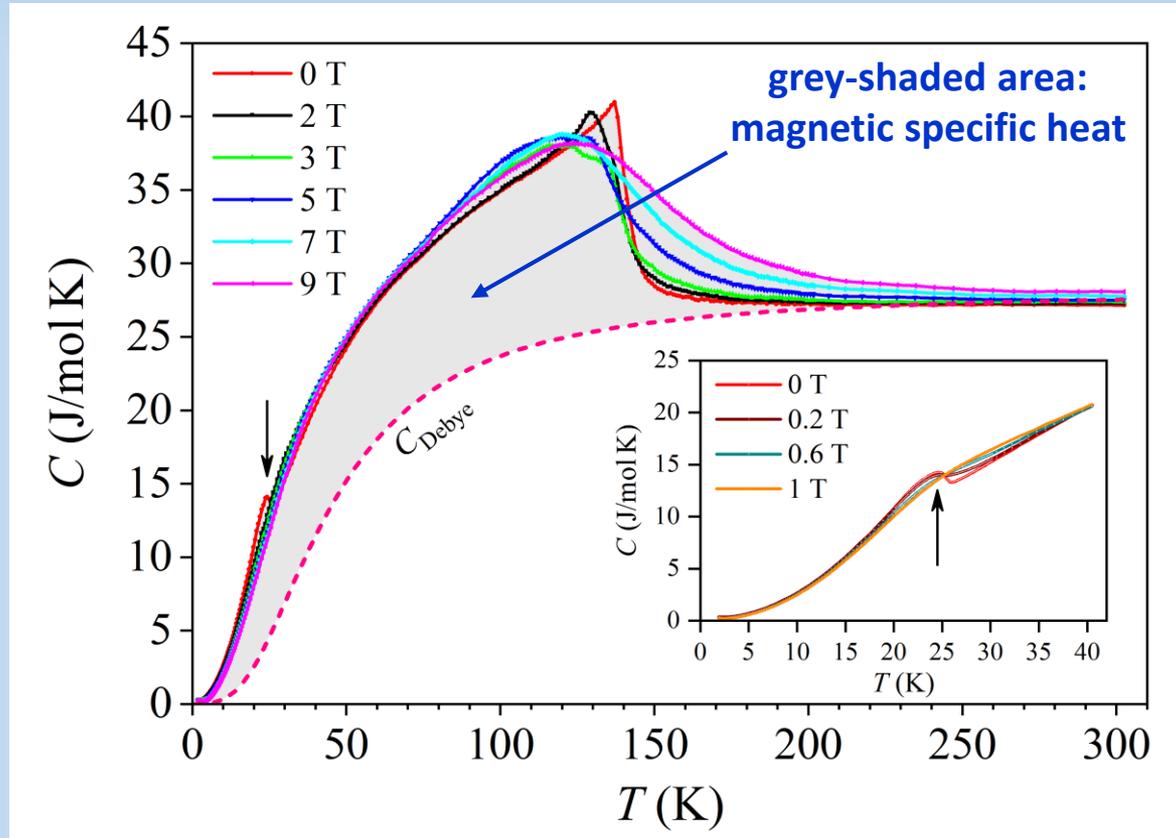

TRM is a measure of “stiffness” of the magnetically frustrated spin system, related to the length scale of the site-averaged magnetic moment correlations  $\langle \vec{J}_i(0) \cdot \vec{J}_j(r) \rangle$ .

FM correlations: large TRM;

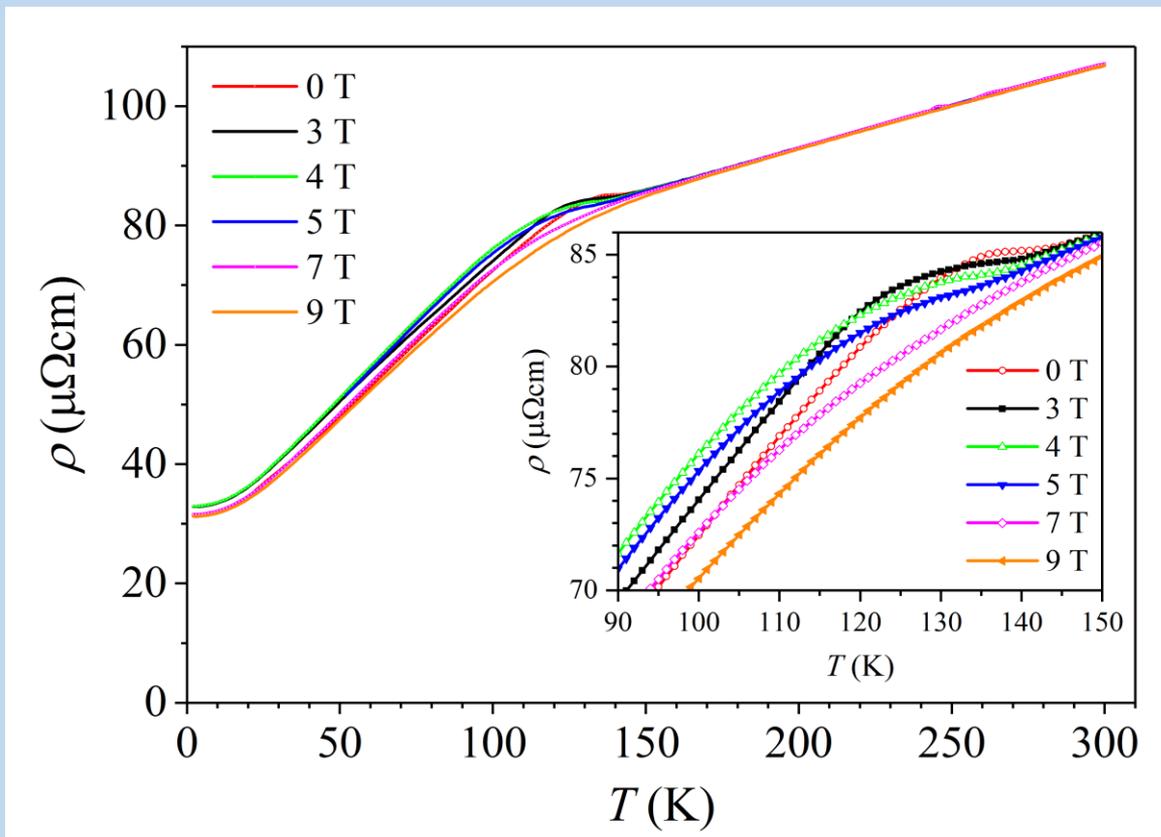

AFM correlations: small (or no) TRM

# Specific heat of Tb-Dy-Ho-Er-Tm hexagonal HEA

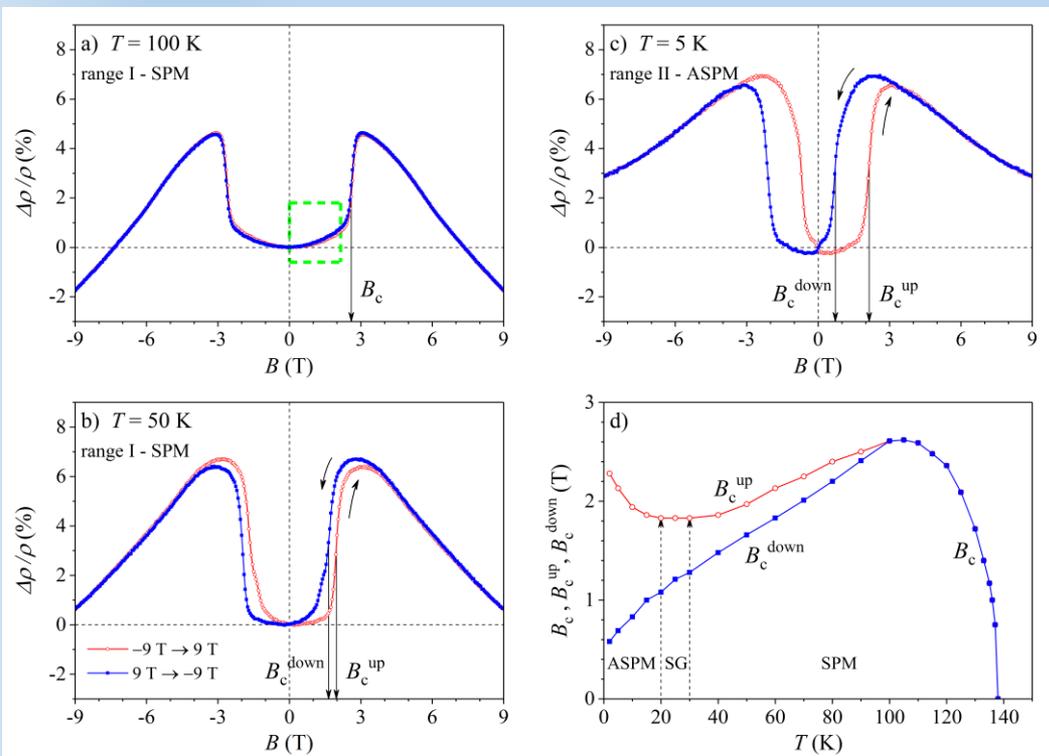

gradual magnetic ordering over a large temperature interval (200 – 2 K)

# Electrical resistivity of Tb-Dy-Ho-Er-Tm hexagonal HEA

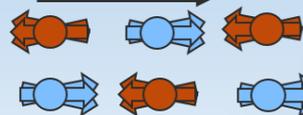

# Magnetoresistance of Tb-Dy-Ho-Er-Tm hexagonal HEA

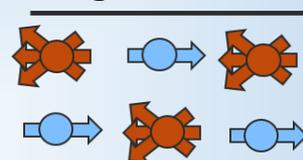

- magnetoresistance changes qualitatively at the critical field  $B_c$ ;
- „up-down“ hysteresis of the critical field.

## ANTIFERROMAGNET

Small field

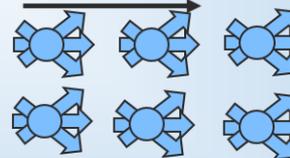

Larger field

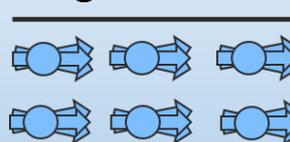

$$\Delta \rho / \rho \propto B^2$$

## PARAMAGNET, FERROMAGNET

Small field

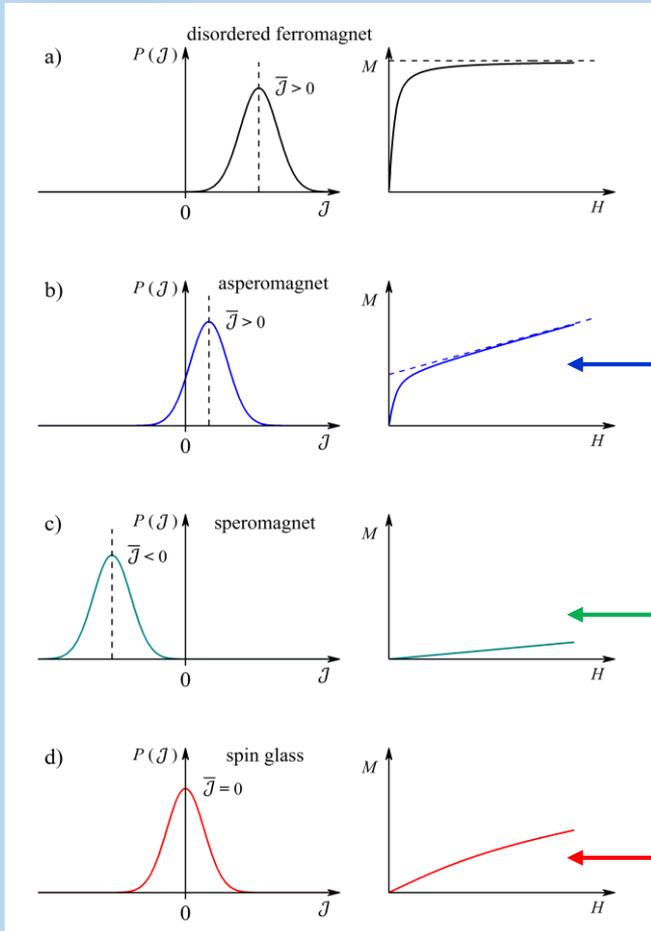

Larger field

$$\Delta \rho / \rho \propto -B$$

# Magnetic ground state of the Tb-Dy-Ho-Er-Tm hexagonal HEA

- asperomagnetic (disordered AFM) at high-T (between 140 and 30 K)
- speromagnetic (disordered FM) at low-T (below 25 K)
- must go through a spin glass state in the temperature range between 30 and 25 K
