

The 125 GeV Higgs boson

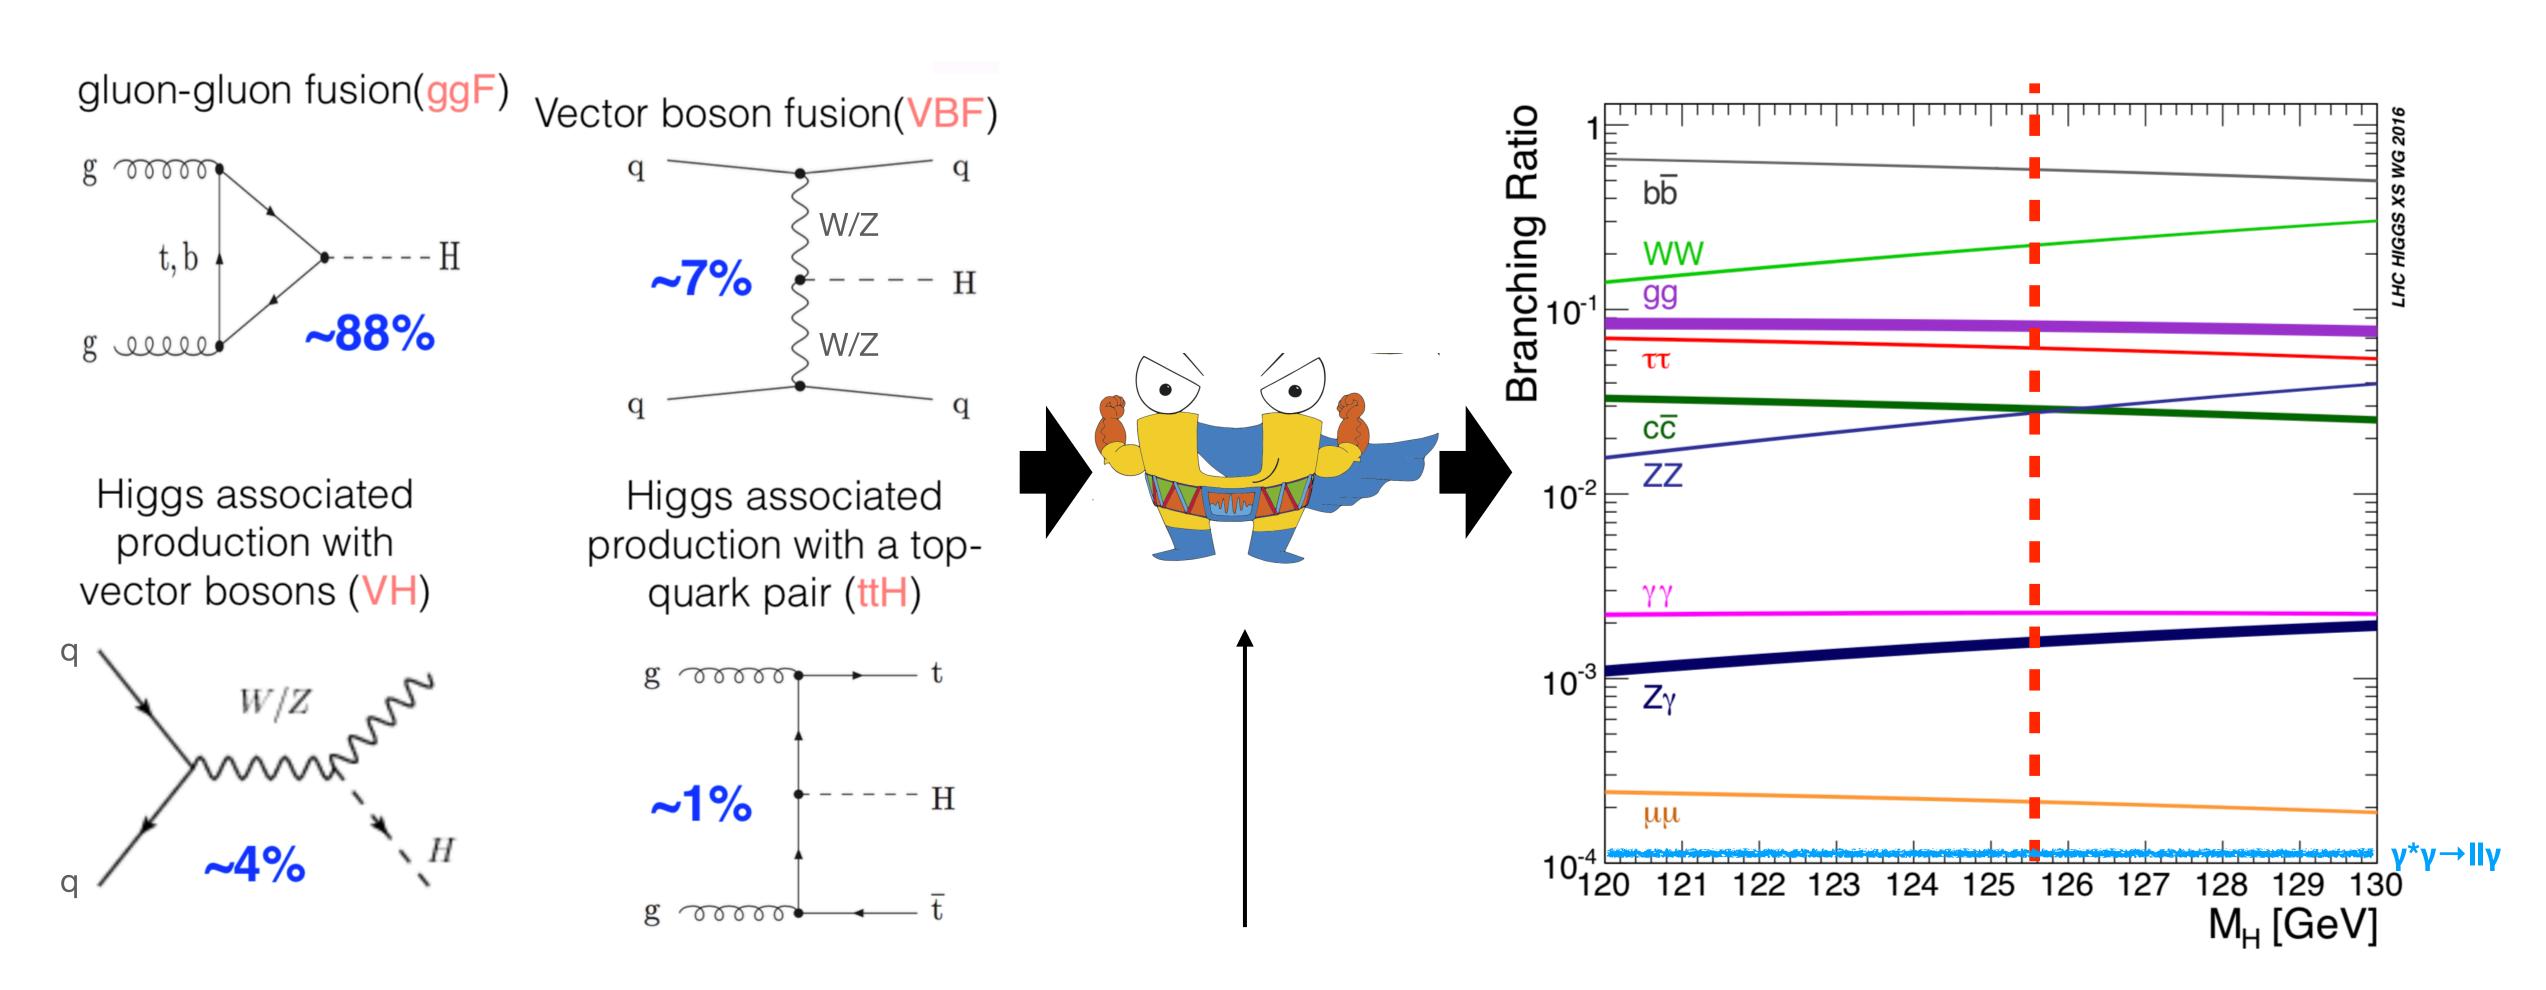

It is the only fundamental scalar with spin 0 we have seen so far

Discovery allows to access a new sector in the Lagrangian:

- Scalar-Gauge boson interactions
- Yukawa couplings
 (new type of interaction)
- Higgs potential: cornerstone of BEH mechanism, not yet probed experimentally

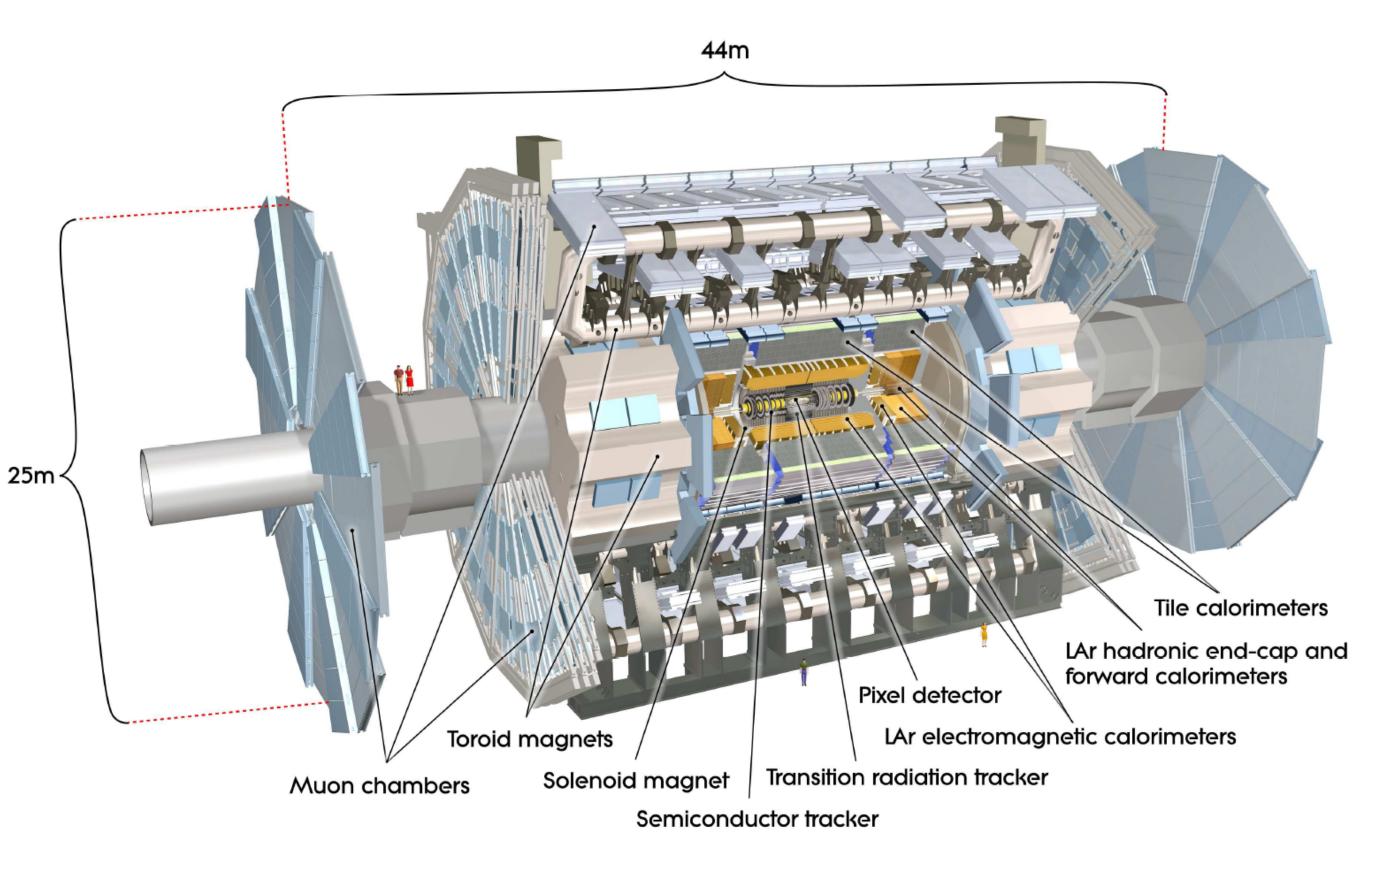

Higgs boson production and decay at the LHC

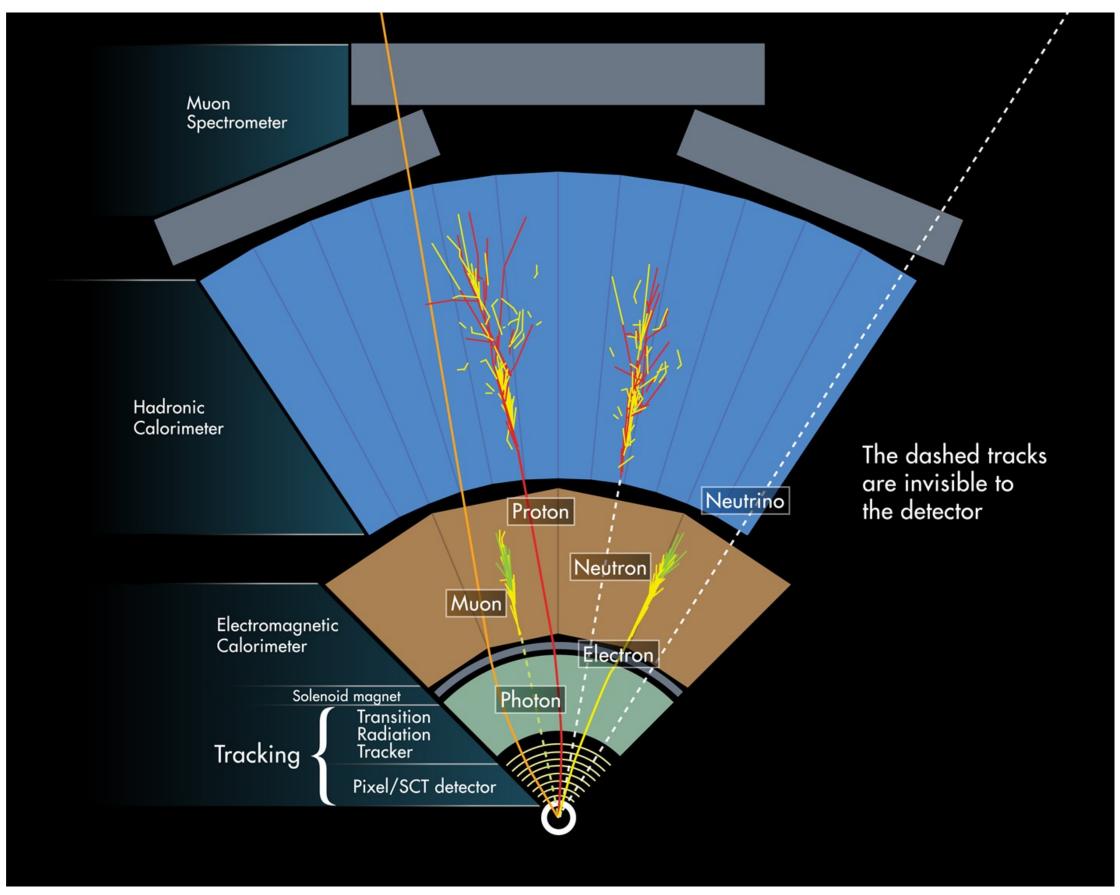

ATLAS Colouring Book - Polski (Polish)

The ATLAS detector at the LHC

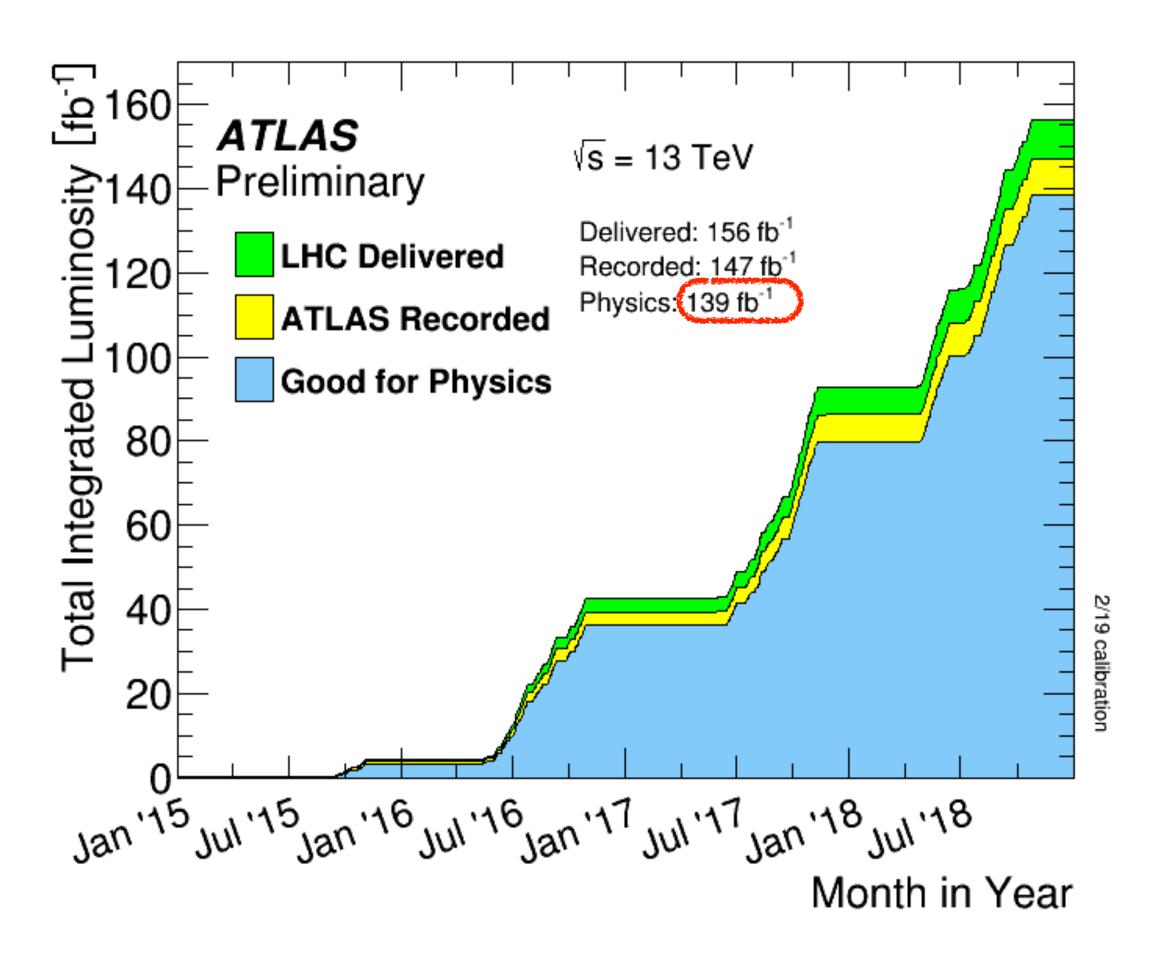

- General-purpose particle physics experiment
 - Designed to exploit the full discovery potential and vast range of physics opportunities that LHC provides

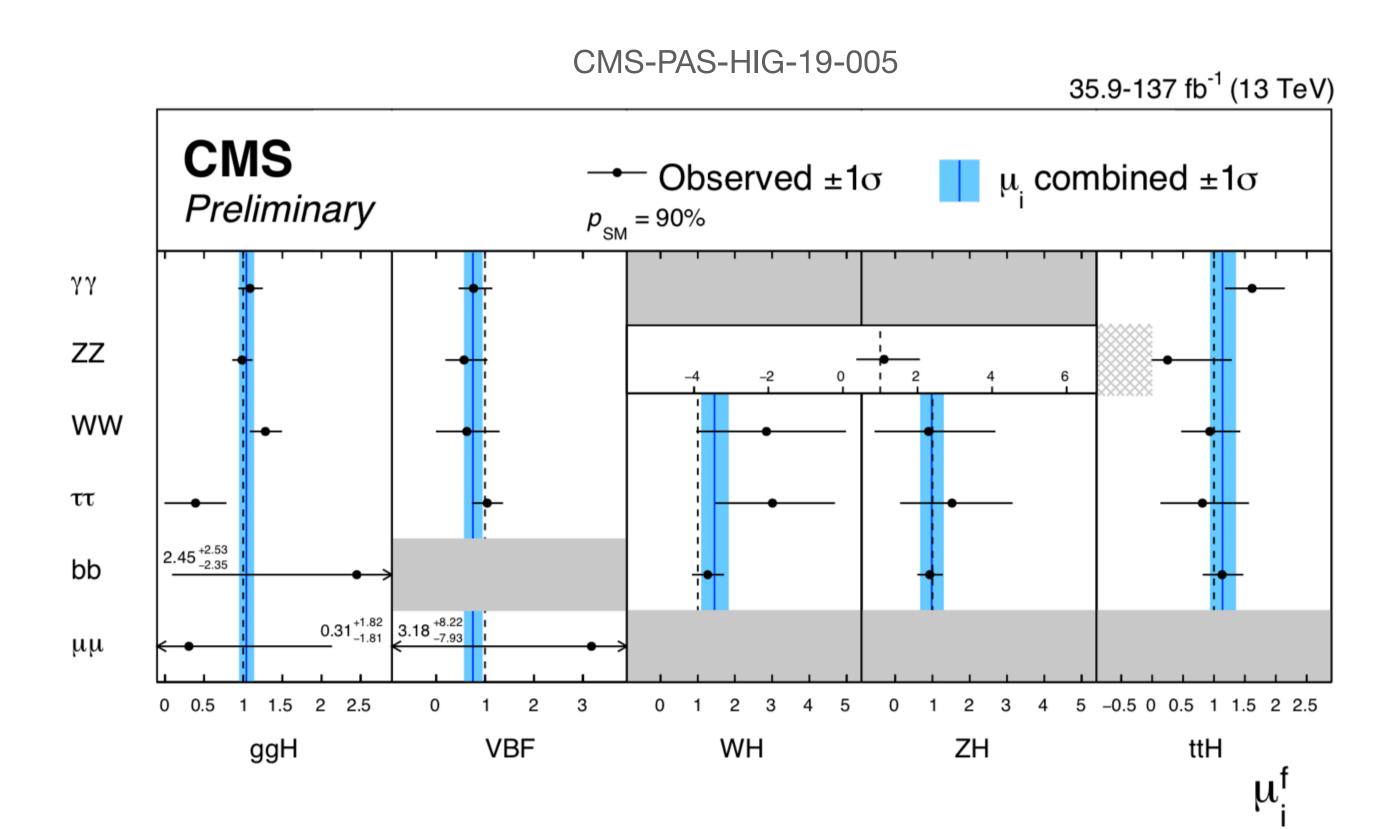

LHC Run 2 period (2015-2018)

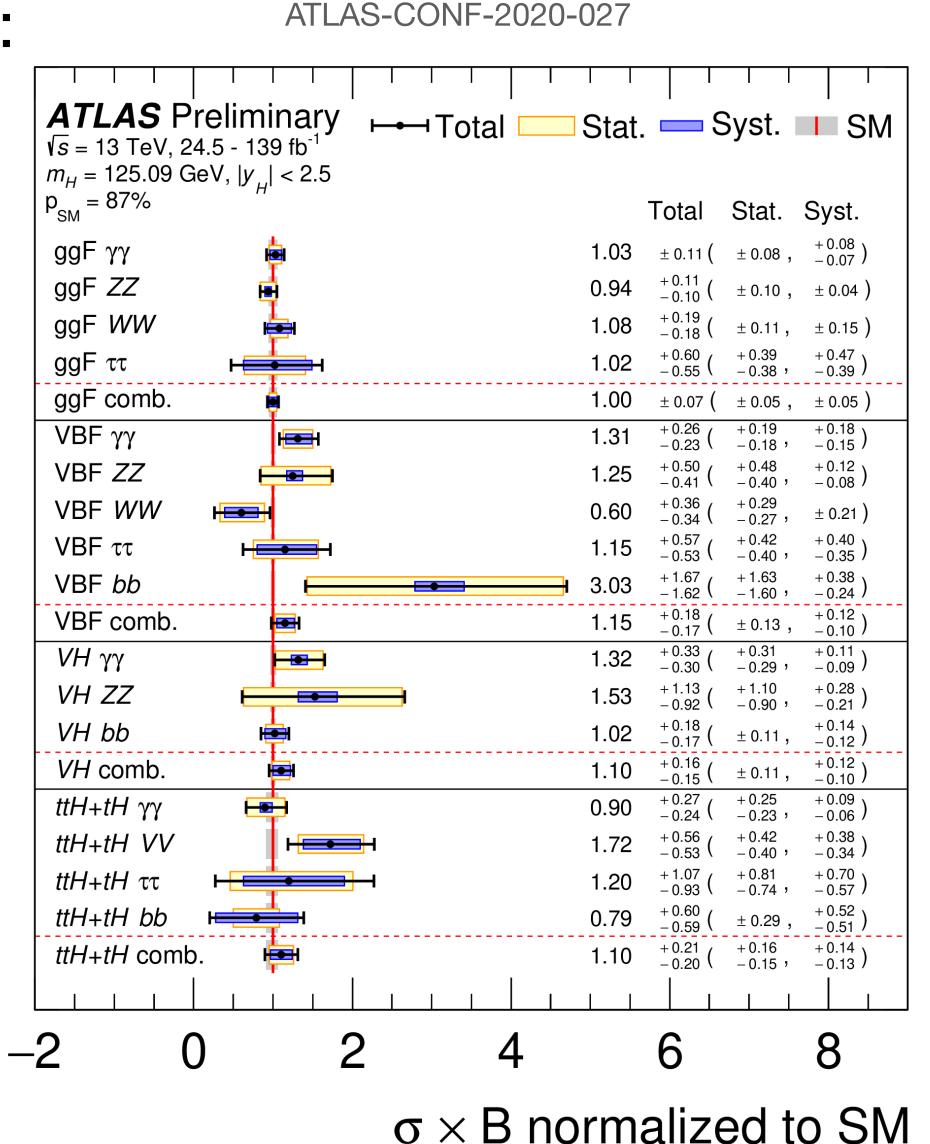

- ATLAS experiment has successfully collected ~140 fb-1 luminosity at pp 13 TeV centre-of-mass energy in the full LHC Run 2 period
 - Big thanks to the CERN accelerator team for the excellent LHC performance!

What do we know about the Higgs boson after LHC Run 2?

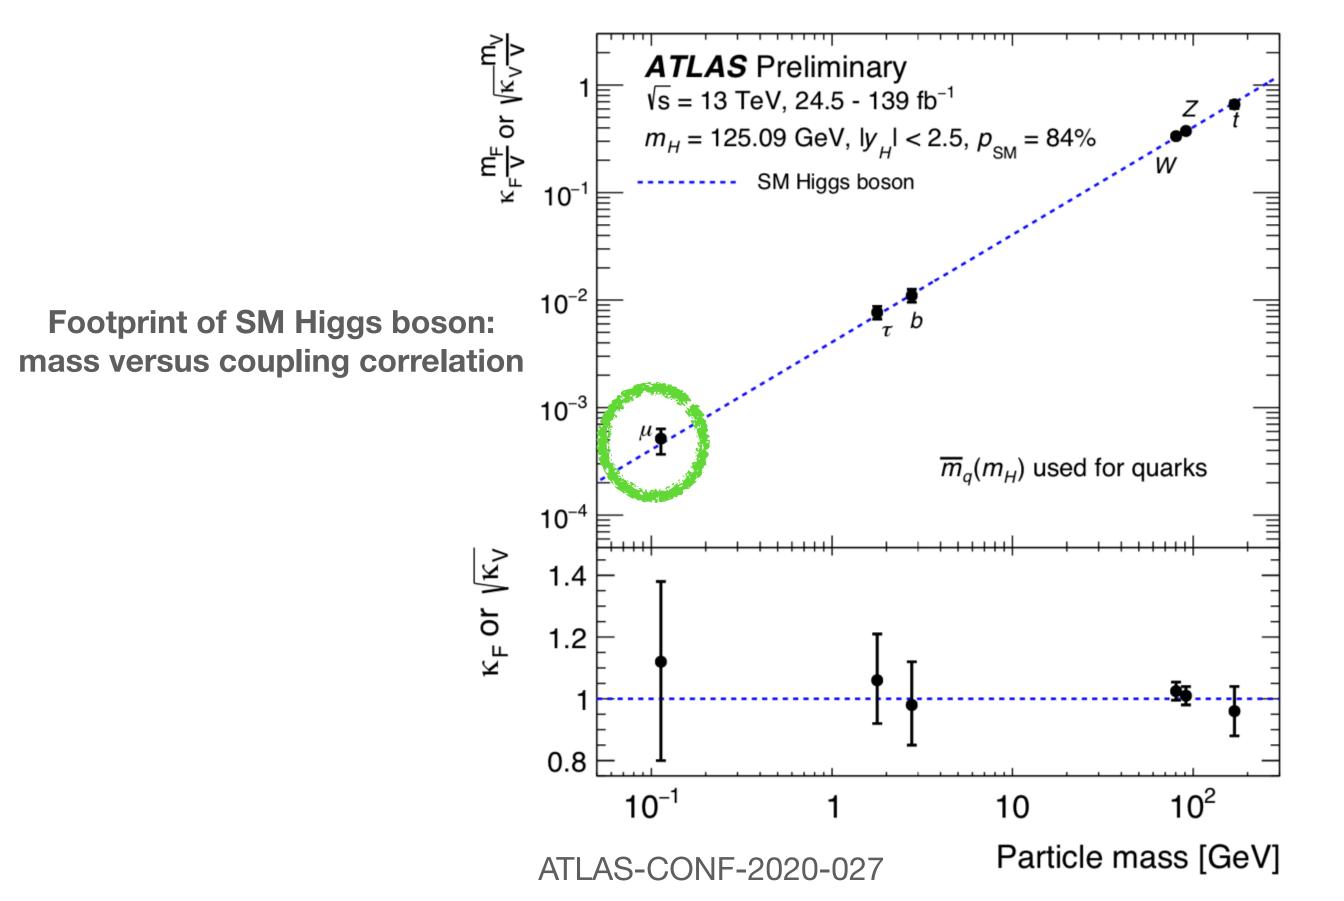

- Inclusive Higgs signal strength combination:
 - $\mu = 1.02 \pm 0.07 [\pm 0.04(th) \pm 0.04(exp) \pm 0.04(stat)]$ (CMS)
 - $\mu = 1.06 \pm 0.07$ (ATLAS)
 - in good agreement with the SM prediction

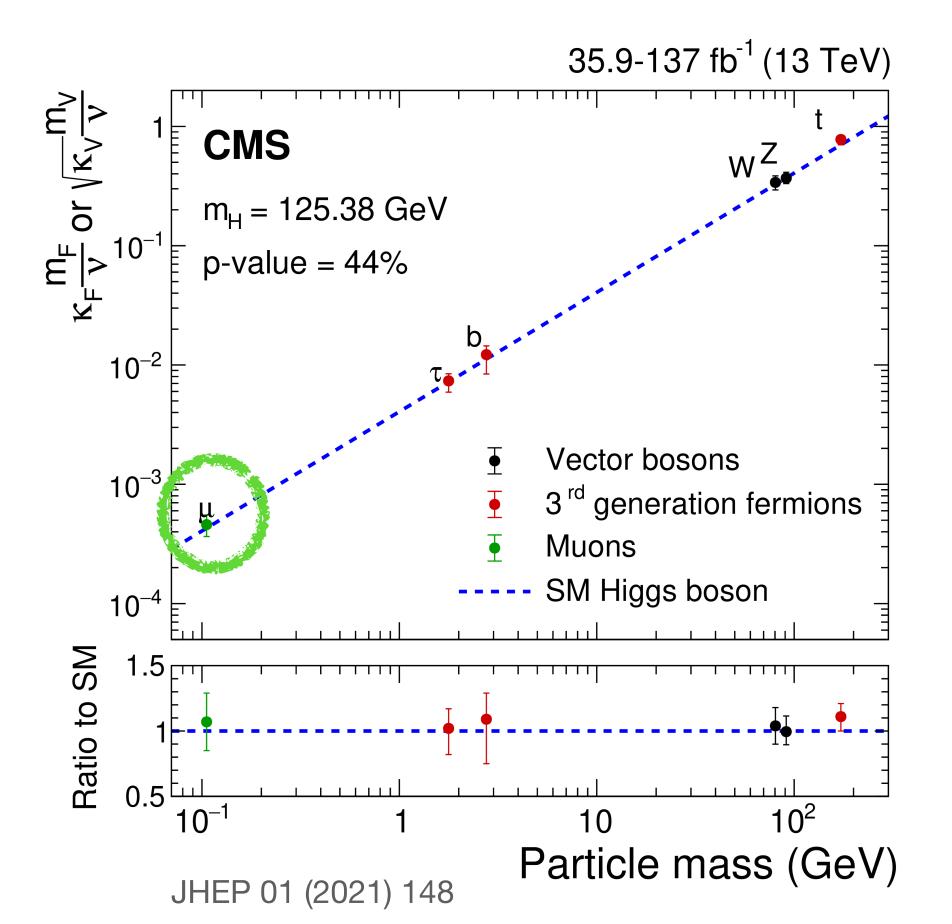

What do we know about the Higgs boson after LHC Run 2?

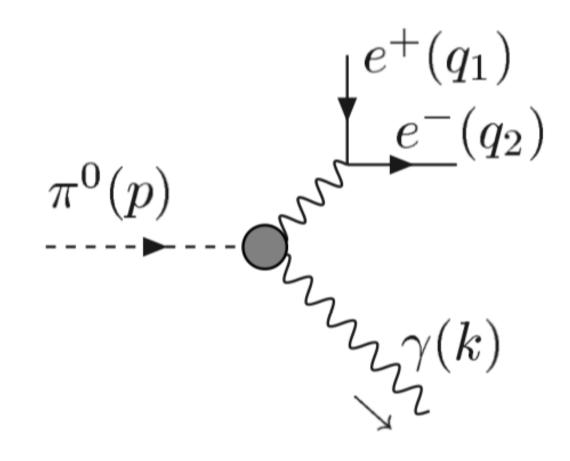

- ATLAS and CMS have performed global fit of coupling modifiers
 - ~6% uncertainty on Higgs to vector boson couplings
 - ~10-15% uncertainty on Higgs to the 3rd generation fermion couplings
 - This includes recent evidence for H→µµ decay

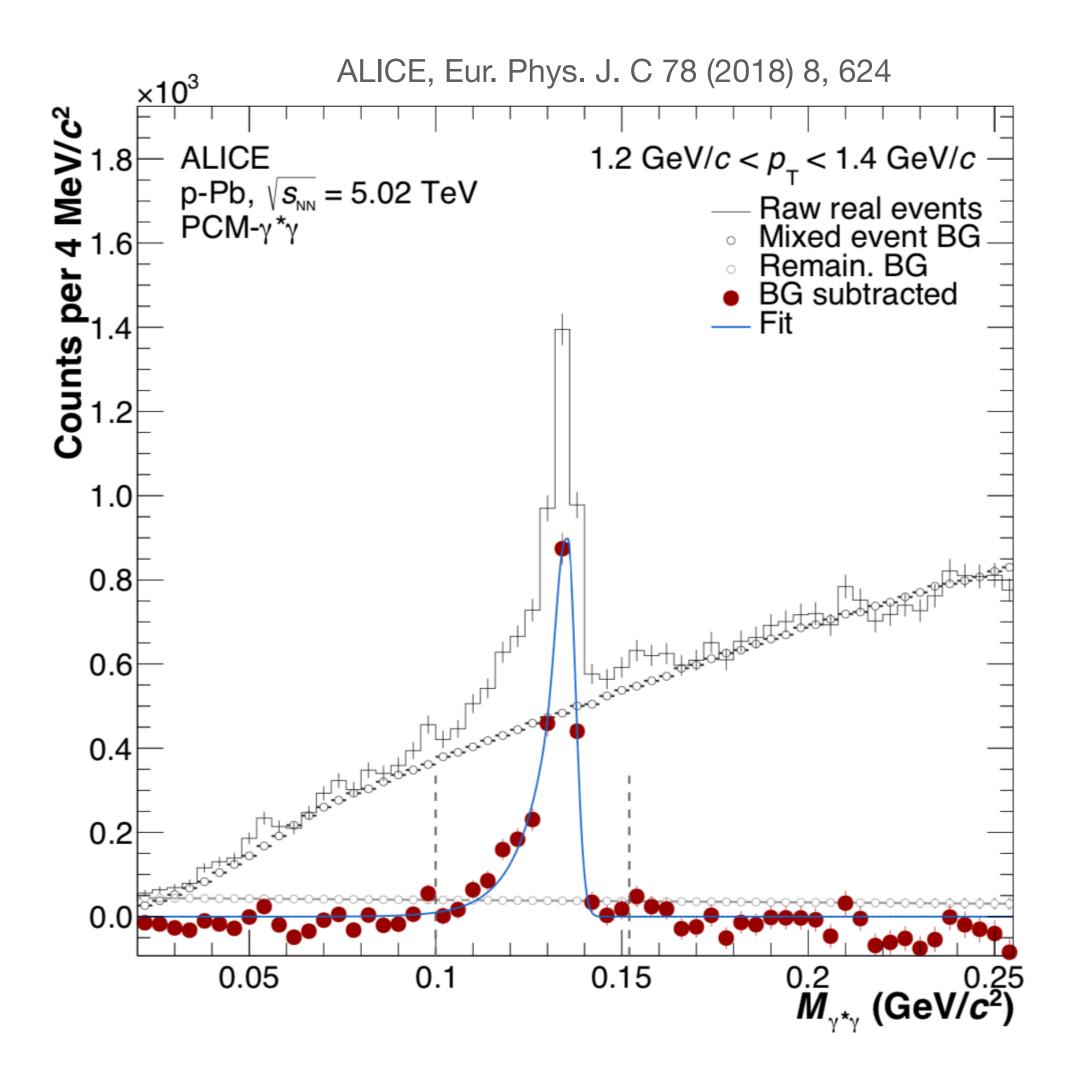

Dalitz decay

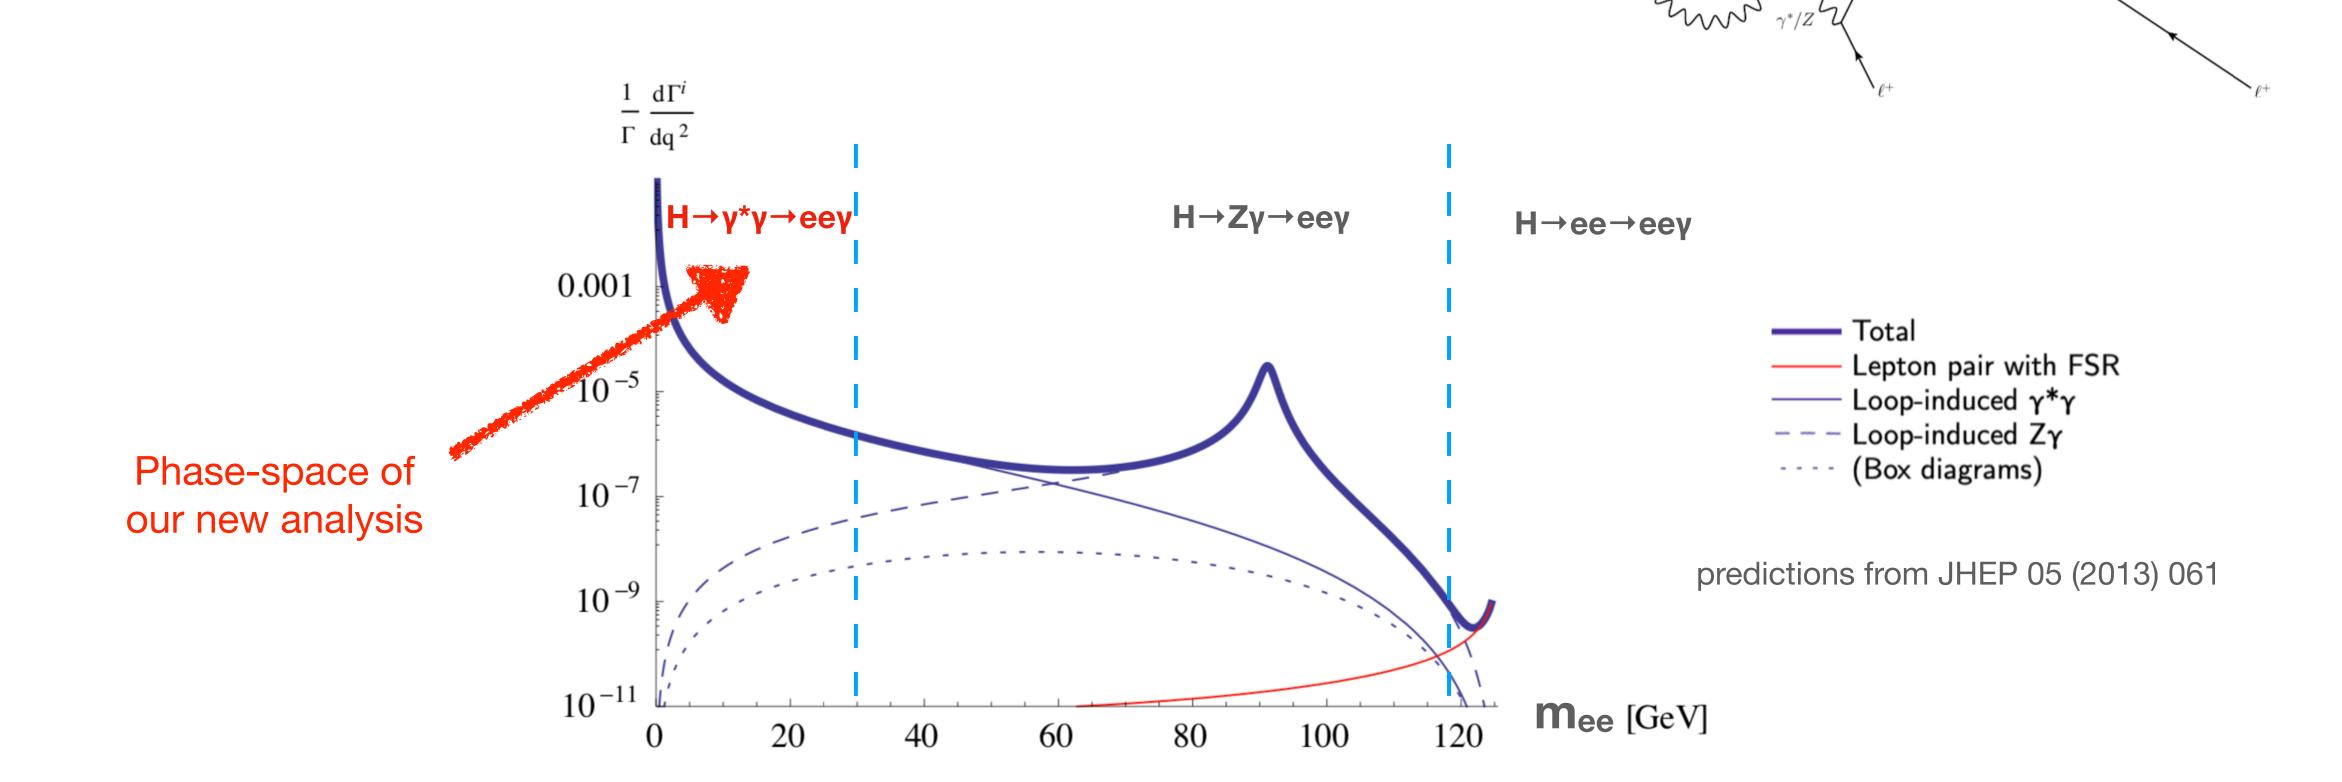

- Traditionally attributed to mesons decaying to two leptons plus a photon
 - Mediated via virtual photon exchange
- Famous example: neutral pion decay
 - $B(\pi 0 \rightarrow \gamma \gamma) = 0.988$
 - $B(\pi 0 \rightarrow ee\gamma) = 0.012$

Higgs Dalitz decay (H→IIγ)

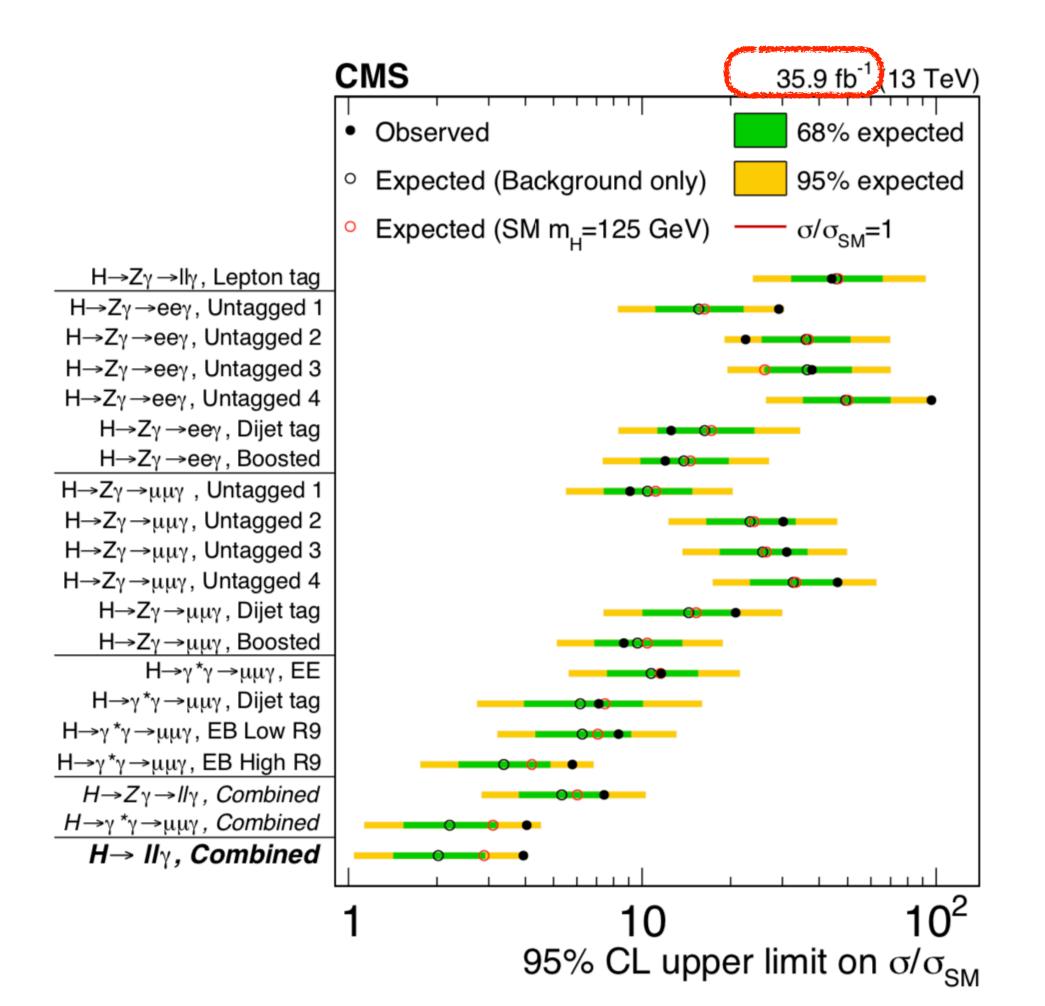

- Very rare decays (**B** < 2×10-4)
- Several processes contribute to the final state
 - Test of exotic couplings through loops
- Diverse final state kinematics

Previous measurements of H→lly

H→IIγ [CMS, JHEP 11 (2018) 152]

Upper limit Zγ: 7.5 * SM (expected w/ Higgs: 6 * SM)
Upper limit γ*γ (μμ): 4 * SM (expected w/Higgs: 3 * SM)

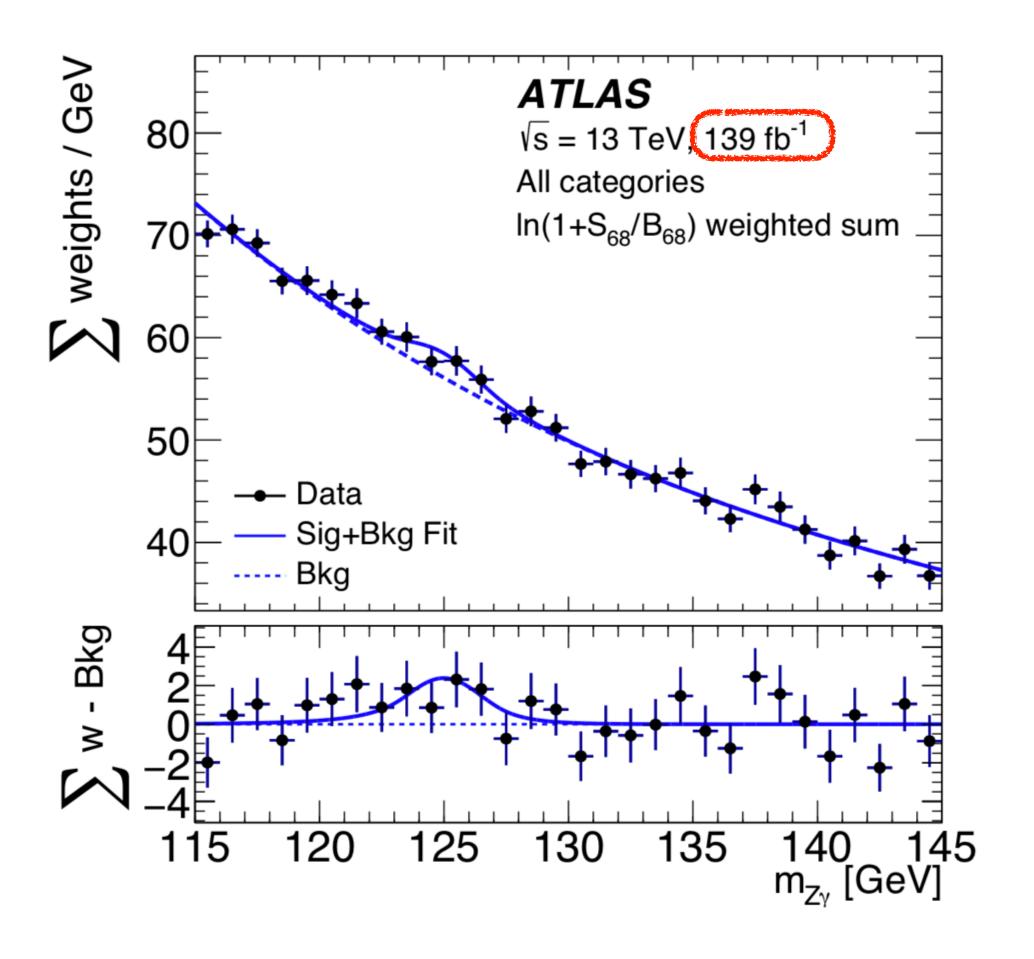

H→Zγ [ATLAS, Phys. Lett. B 809 (2020) 135754]

mll: Z boson mass +/-10 GeV

significance: 2.2 σ (expected w/ Higgs: 1.2 σ)

upper limit: 3.6 * SM (expected w/ Higgs: 2.6 * SM)

New search for H→IIy decays with ATLAS

arXiv:2103.10322

EUROPEAN ORGANISATION FOR NUCLEAR RESEARCH (CERN)

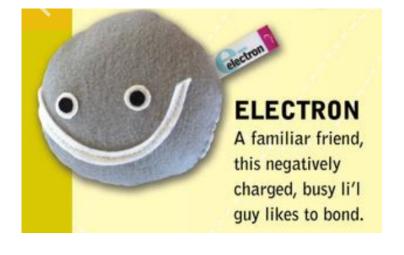

Evidence for Higgs boson decays to a low-mass dilepton system and a photon in pp collisions at $\sqrt{s} = 13$ TeV with the ATLAS detector

The ATLAS Collaboration

Search for H→IIy decays at low-m_{II} with ATLAS

- Rough sketch of analysis procedure:
 - Object and event selection + categorisation (Step 1)
 - Signal and background parameterisations (Step 2)
 - Simultaneous fit to all categories (Step 3)

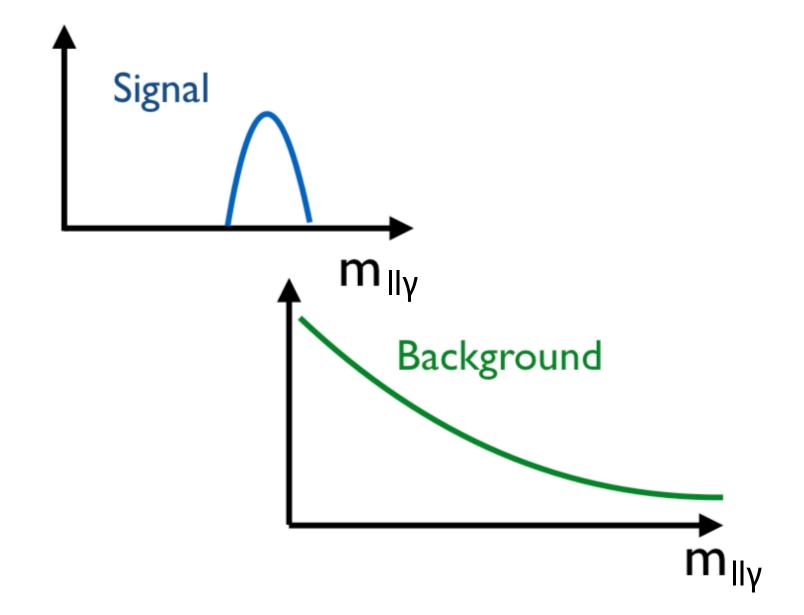

Step 1

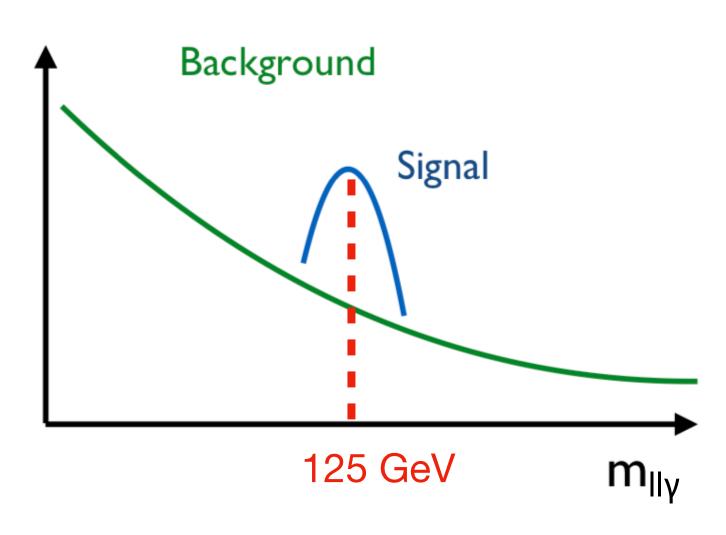

Step 2

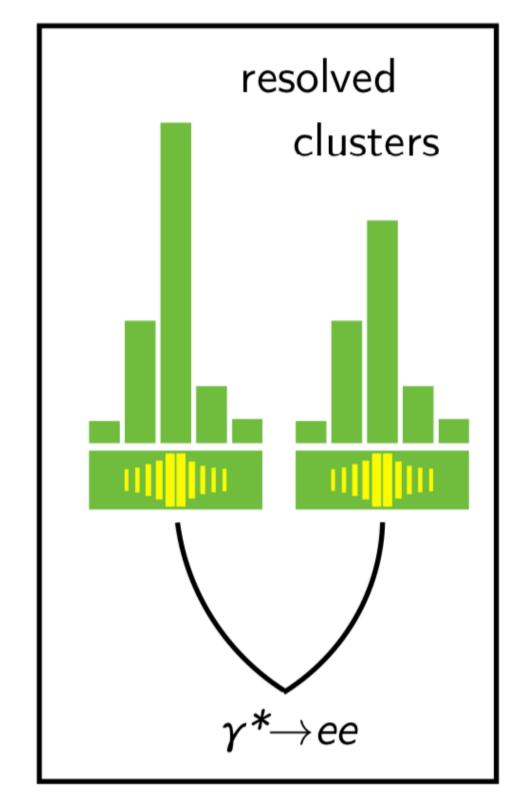

Step 3

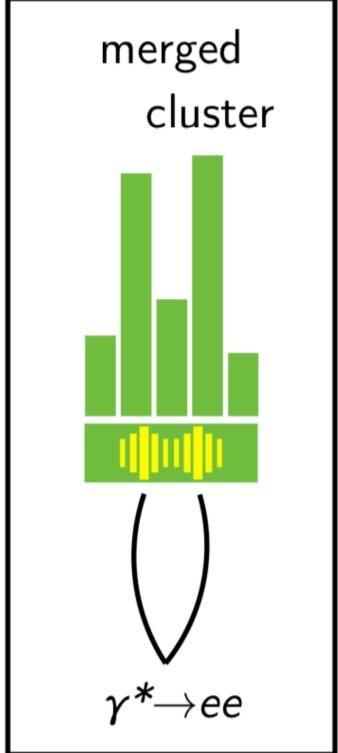

Event selection

Trigger:

- Combination of single-lepton, 2I, γ+I, γγ, γ+2I triggers is used
- Dedicated merged-ee + γ trigger is also employed
- Object selection:
 - Photons: Isolated with p_T > 20 GeV
 - Muons: Isolated (leading) with p_T > 3 (11) GeV
 - Electrons: Isolated (leading) with p_T > 4.5 (13) GeV
 - Merged-ee: isolated with p_T > 20 GeV
 - Jets: p_T > 25 GeV
- Select an opposite-sign same flavor lepton pair (μμ or ee or merged-ee) + γ
 - m_{II} < 30 GeV and veto J/Psi and Upsilon mass range
 - Relative p_T cuts: $p_{T,II}/m_{II\gamma} > 0.3$, $p_{T}(\gamma)/m_{II\gamma} > 0.3$

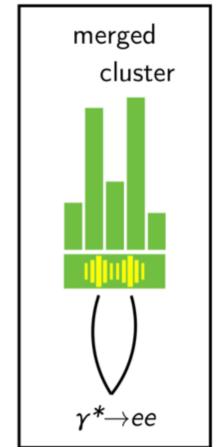

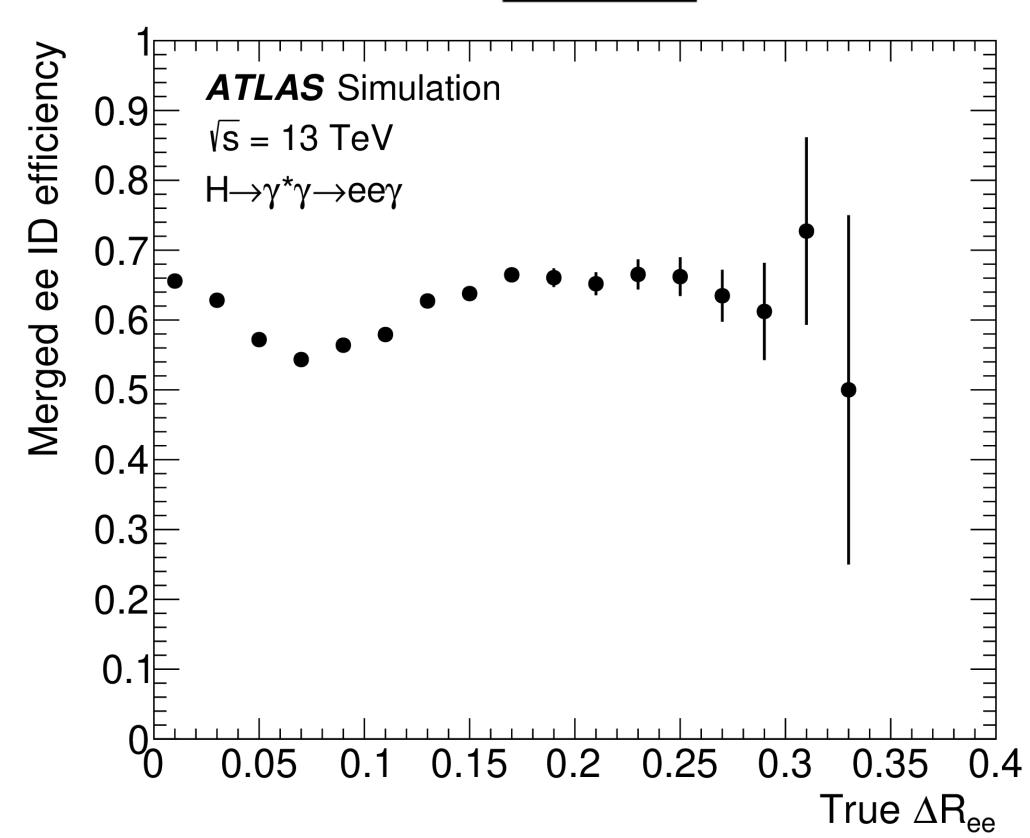

Merged-ee identification

- The algorithm
 - Due to the low mass of the dielectron pair they are often collimated
 - Requires dedicated identification (ID) to ensure reasonable efficiency is maintained vs angular separation

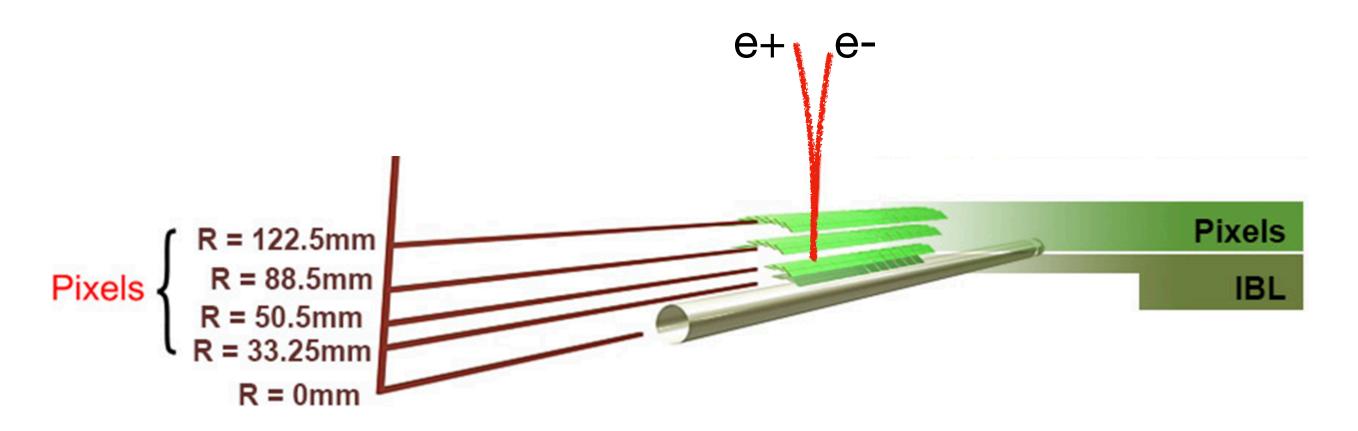

- EM shower shapes
- Vertex contracted from the 2 selected tracks
- Vertex-cluster and track-cluster matching requirements
- Additional cuts to reduce background from single electrons
- Optimisation is performed using multivariate analysis techniques

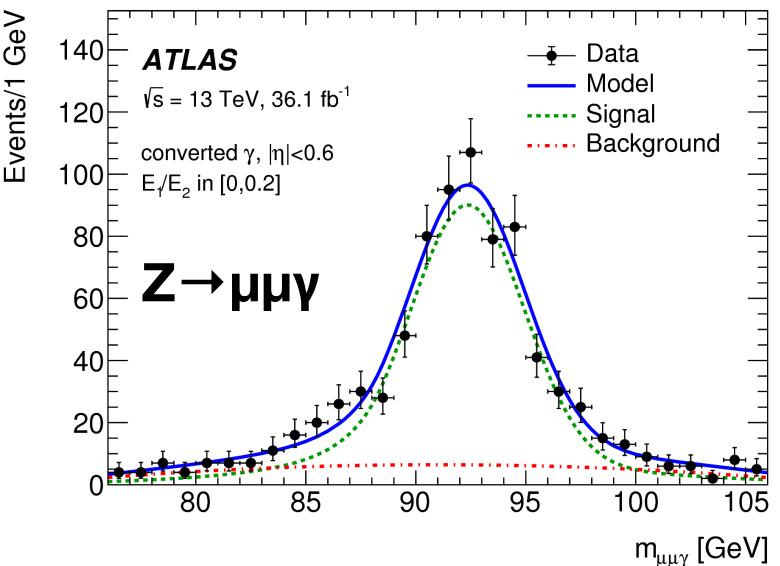

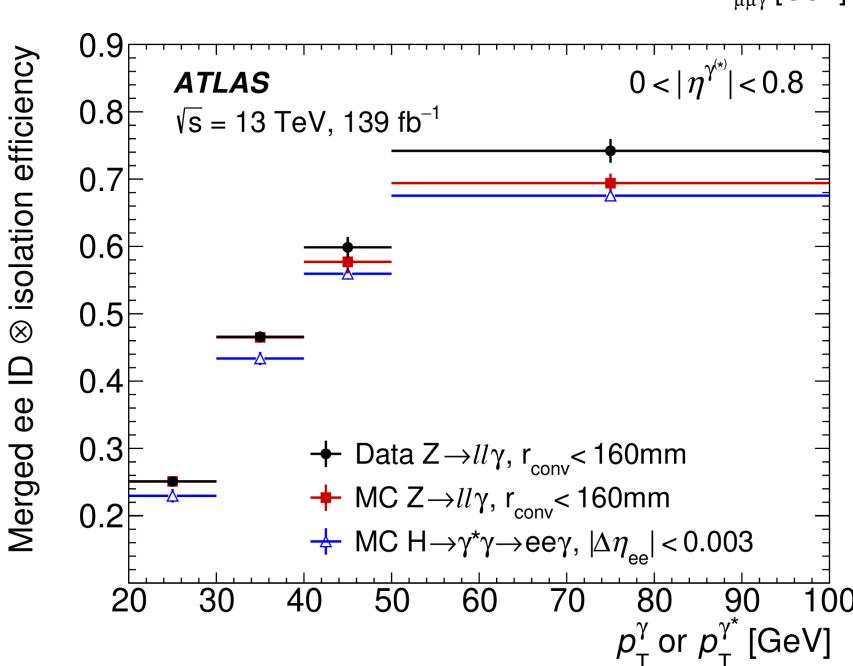

Merged-ee identification and calibration

- Use Z→IIγ events to perform efficiency measurements
 - Consider only converted photons, with conversion radius <160 mm to have an object similar to γ*
 - Extract efficiency of combined merged-ee PID + isolation requirements
- Energy calibration
 - Merged-ee objects are similar to converted photons
 - Calibrate γ* as an early converted photon with radius 30 mm

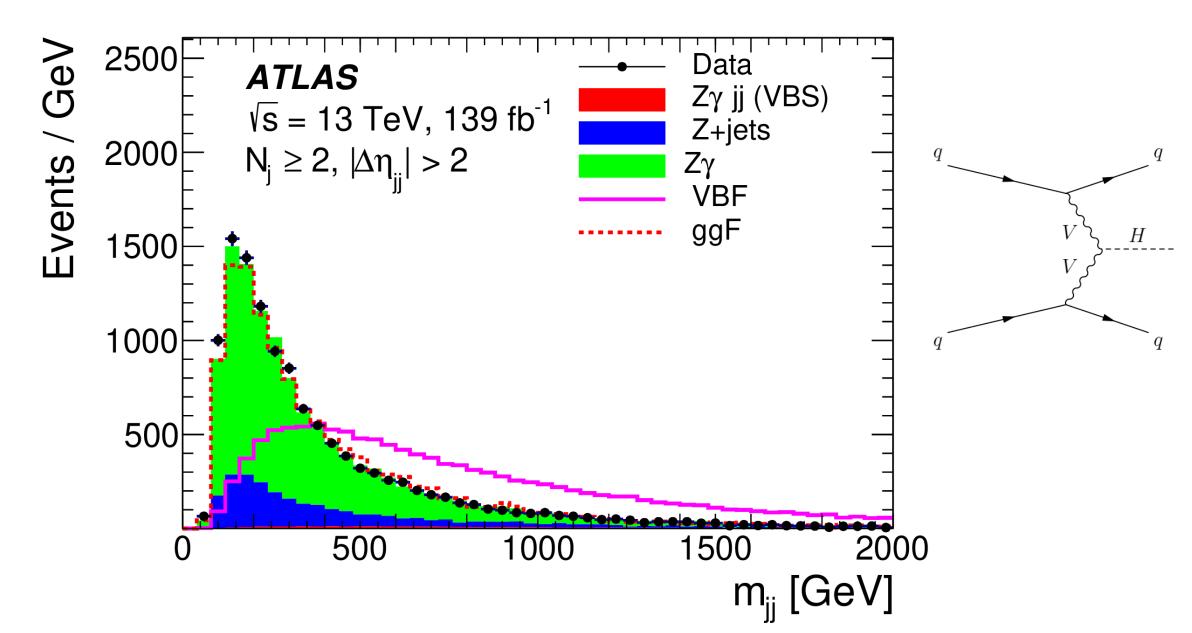

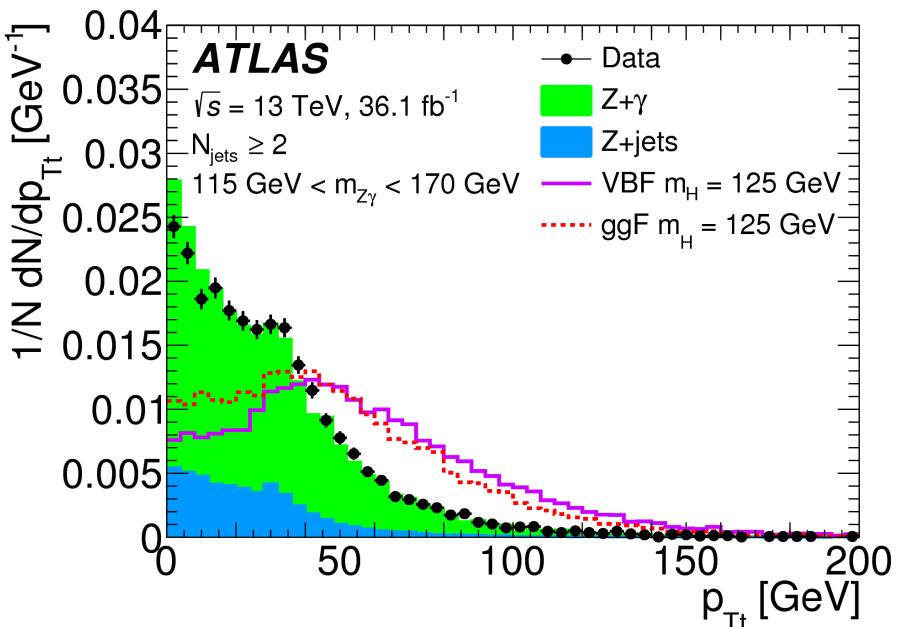

Event kinematics

- In VBF process, valence quarks scatter resulting in a large dijet invariant mass
 - Jets in non-resonant IIγ are mostly from gluon radiation and have lower invariant masses

- $\mathbf{p_{Tt}} = 2|\mathbf{p_{T,II}}||\mathbf{p_{T,\gamma}}| \sin \Delta \phi_{II,\gamma} / \mathbf{p_{T,II\gamma}}$
 - While correlated with Higgs p_T,
 p_{Tt} has lower experimental uncertainties & lower correlation with the Higgs boson mass
 - Larger values for signal than the non-resonant backgrounds

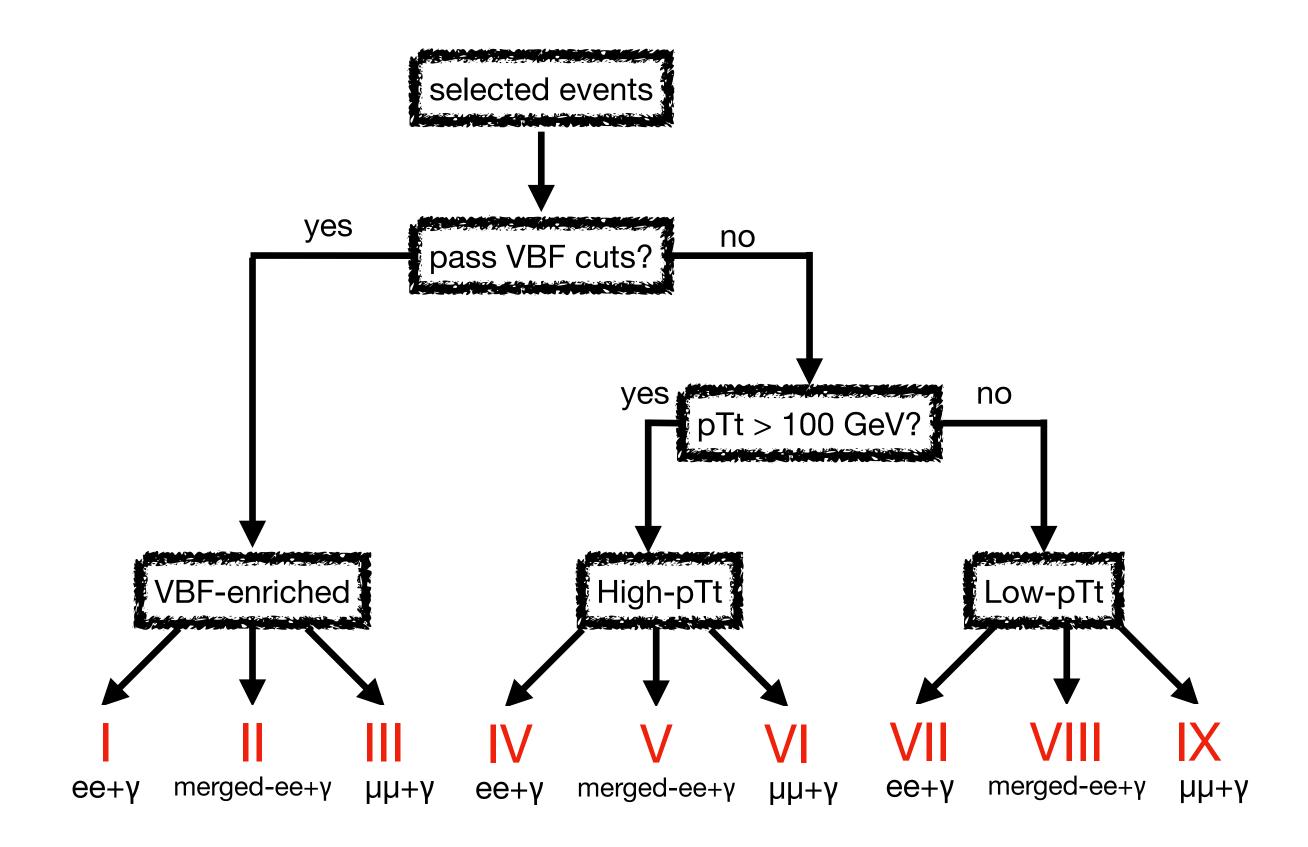

Event categorisation

• For each signature 3 kinematic categories are created (9 categories in total)

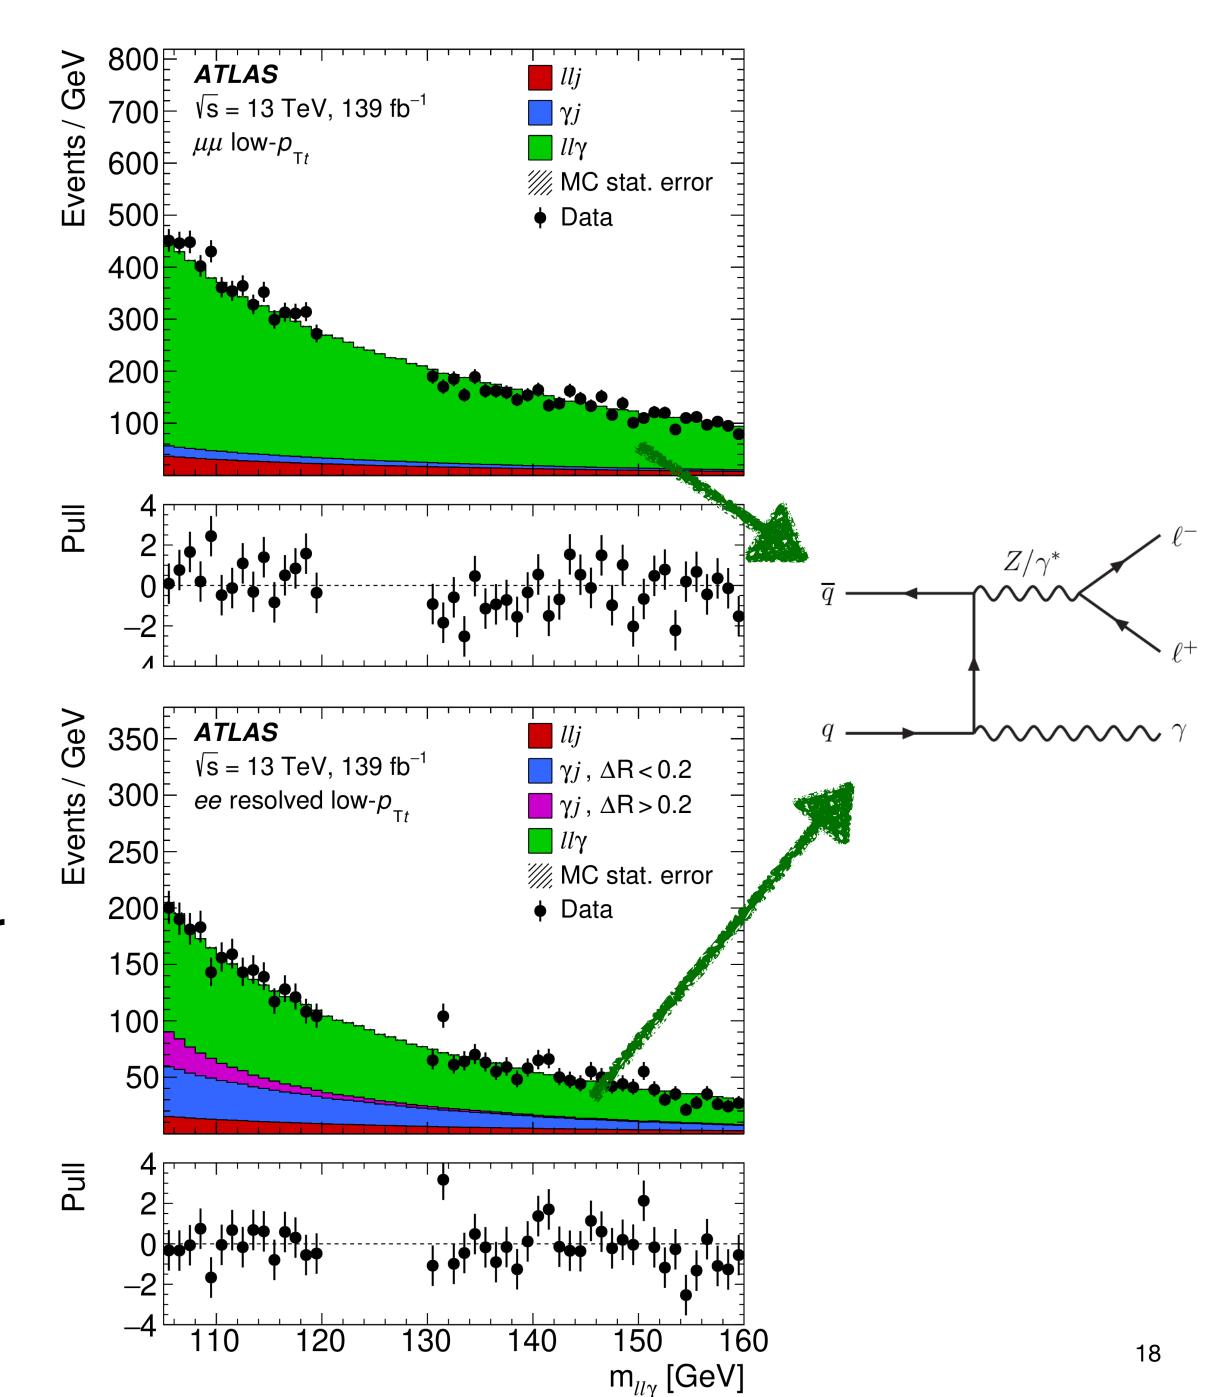

VBF-enriched

- >= 2 jets
- $m_{jj} > 500 \text{ GeV}$
- $\Delta \eta_{jj} > 2.7$
- $\Delta \phi(ll\gamma,jj) > 2.8$
- •
- High-p_{Tt}
 - !VBF-enriched & p_{Tt} > 100 GeV
- Low-ptt
 - Remaining events

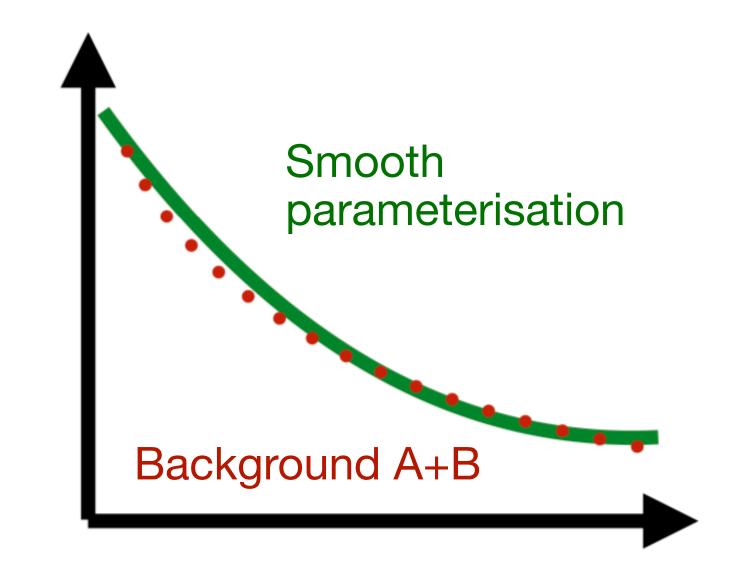

Background studies

- Estimated backgrounds are used for:
 - Optimization
 - Background fit choice
 - Note the final background estimation is from data
- Non-resonant Ilγ (prompt photons)
 - Obtained from MC simulation
- Fake background (jets faking photons or jets faking leptons)
 - Obtained from data control regions
 - Relative fraction is also estimated from data

Background modeling

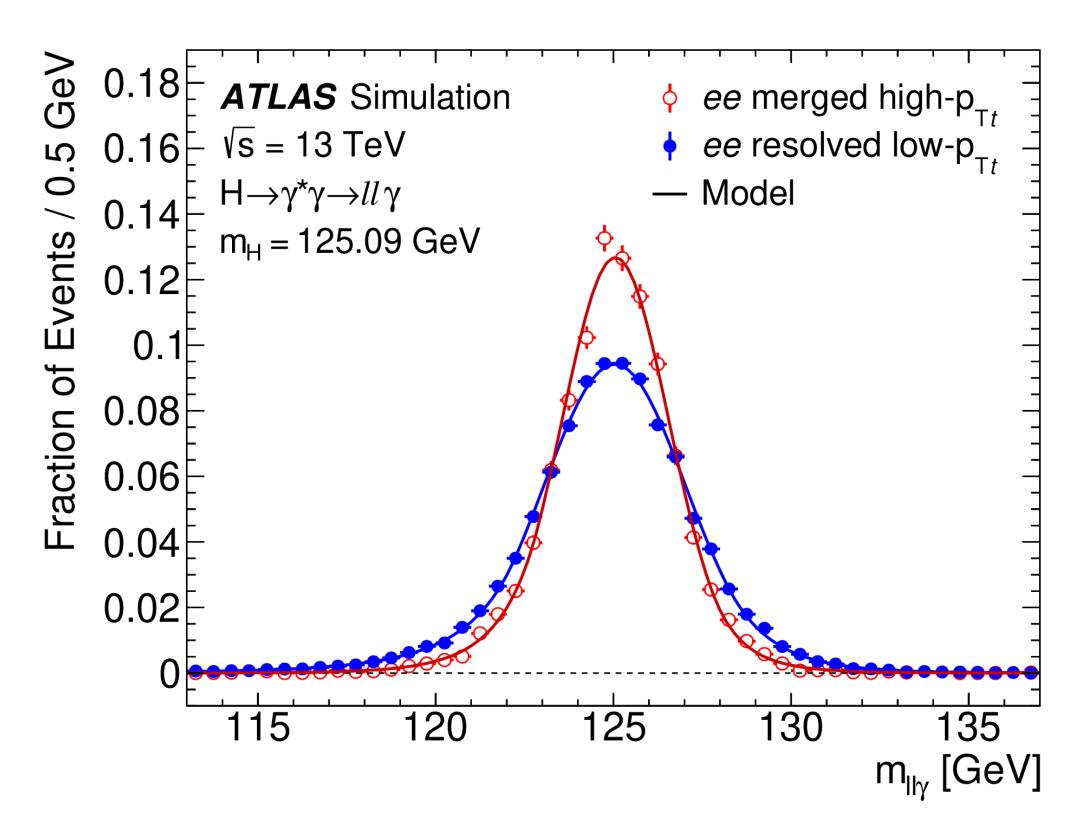

- Parameterisation of the background shape is performed using parametric functions
 - Choices of functions: exponential, Bernstein, and power functions
- Background function choice
 - Signal+Background fit to expected background templates
 - Functions with low bias and with low degrees of freedom are preferred
 - Any bias in the signal strength is taken as a systematic uncertainty

Channel	Function
μμ VBF-enriched	mα
μμ High-p _{T-Thrust}	mα
μμ Low-p _{T-Thrust}	e ^{αm+βm×m}
Merged e VBF-enriched	mα
Merged e High-pt-Thrust	mα
Merged e Low-pt-Thrust	e ^{αm+βm×m}
Resolved e VBF-enriched	e ^{αm}
Resolved e High-p _{T-Thrust}	mα
Resolved e Low-pT-Thrust	m ^α

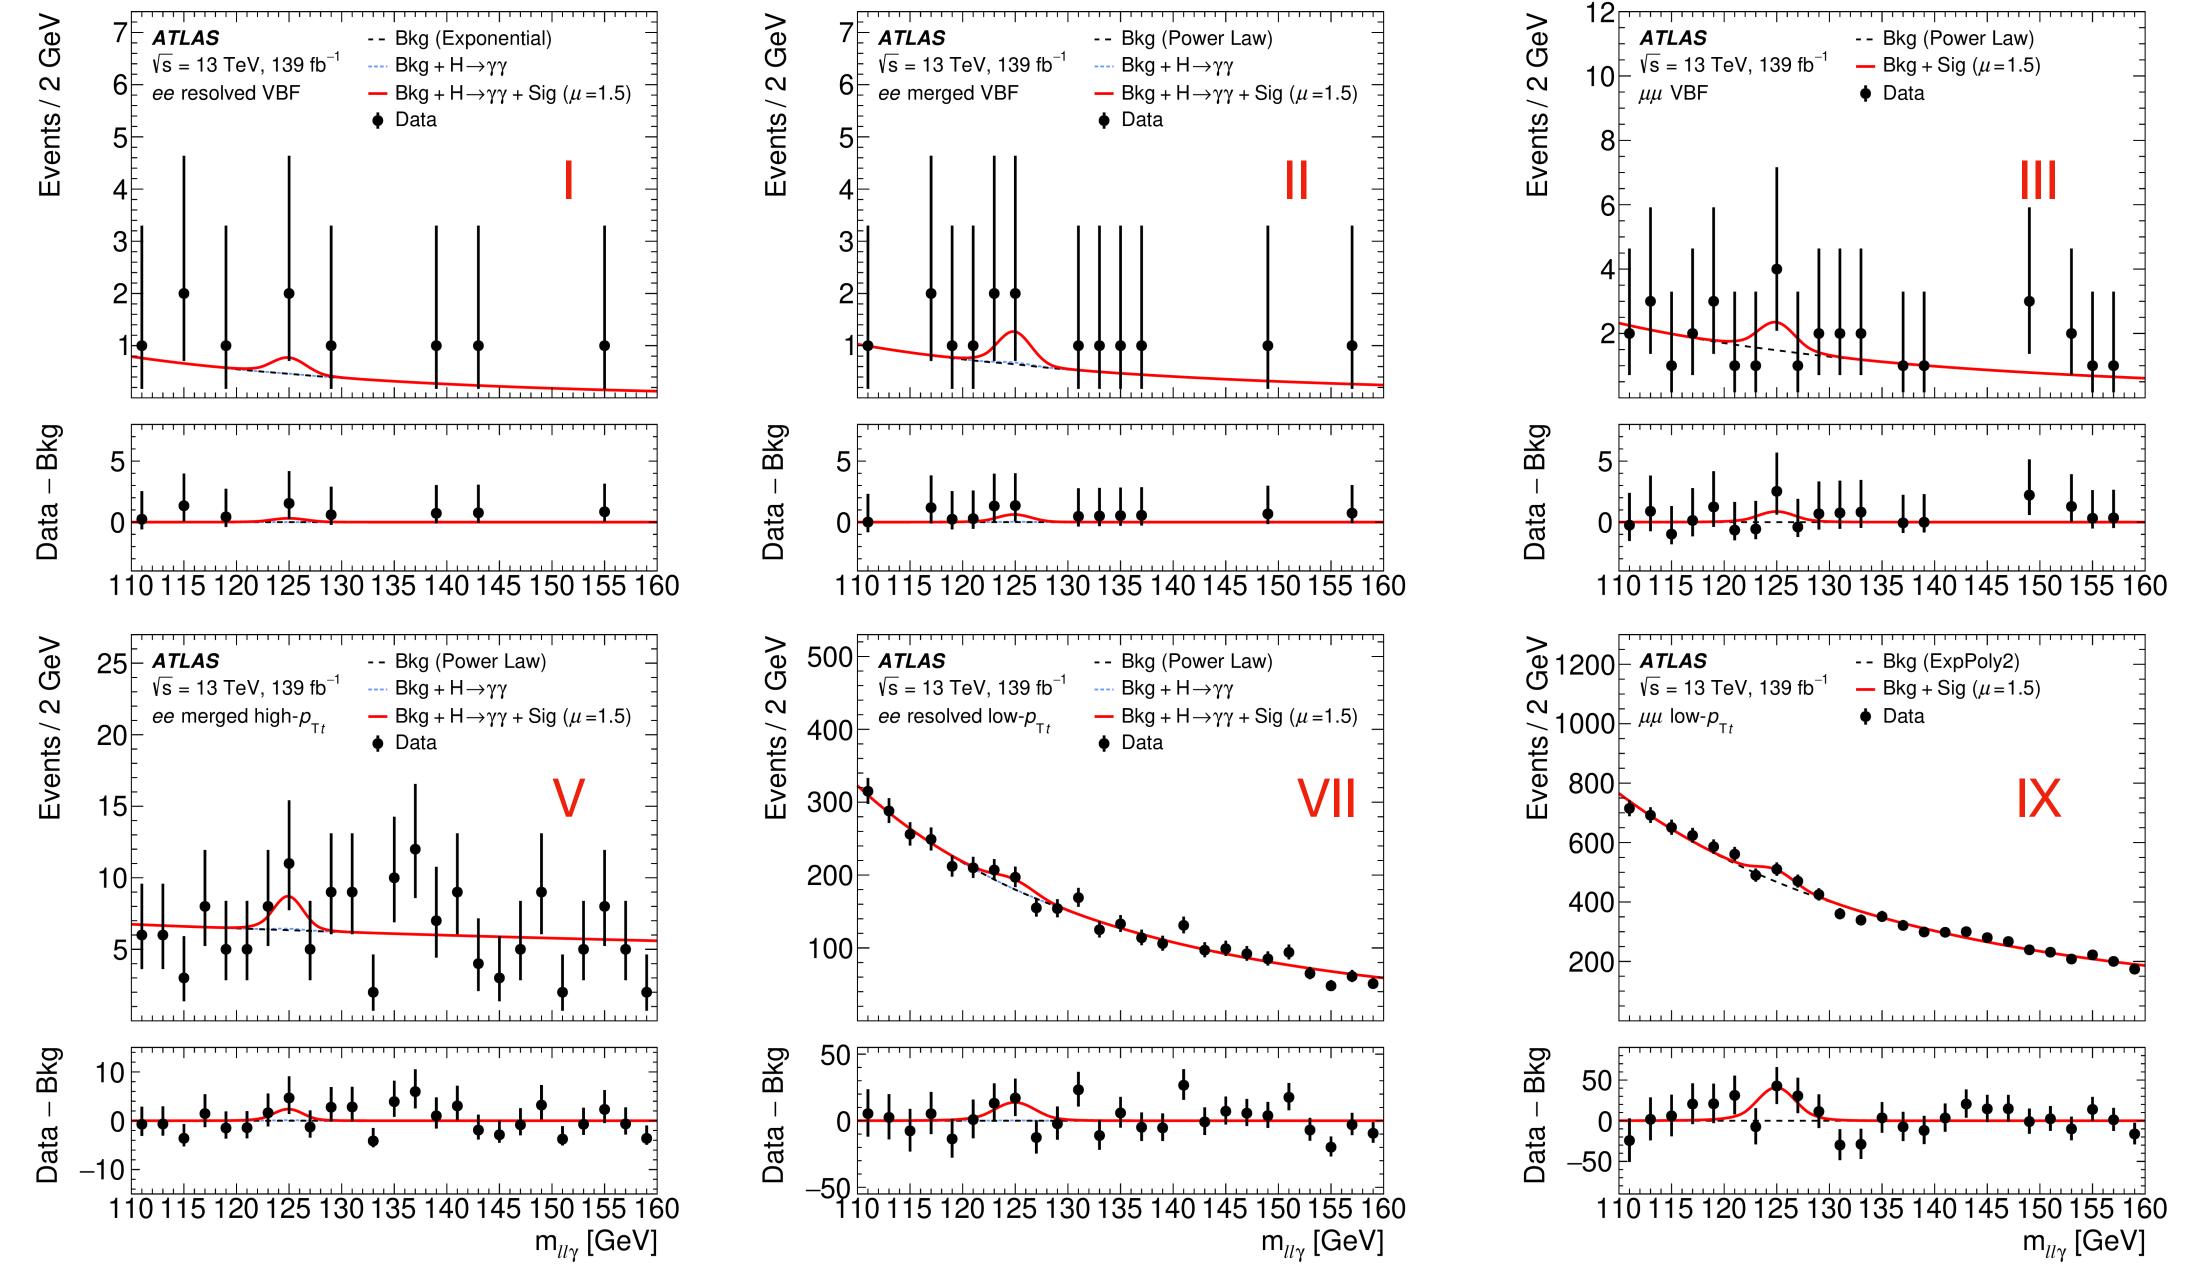

Signal modeling

- Double-sided Crystal Ball function (DSCB) is used to model the signal in each event category
 - Gaussian core + (asymmetric) power-law tails

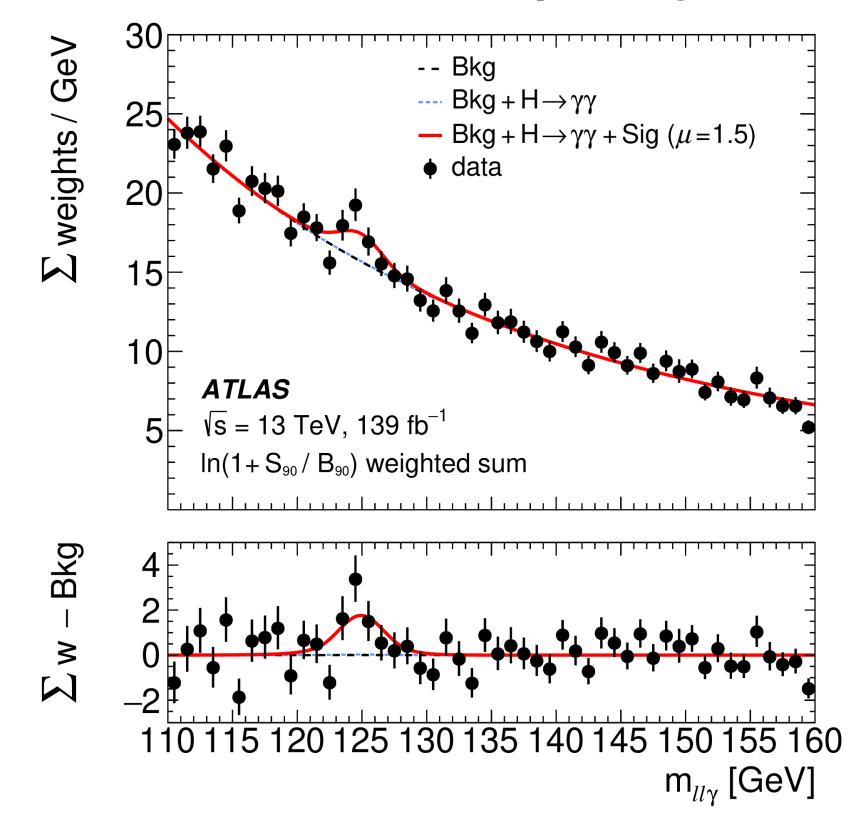

Signal regions

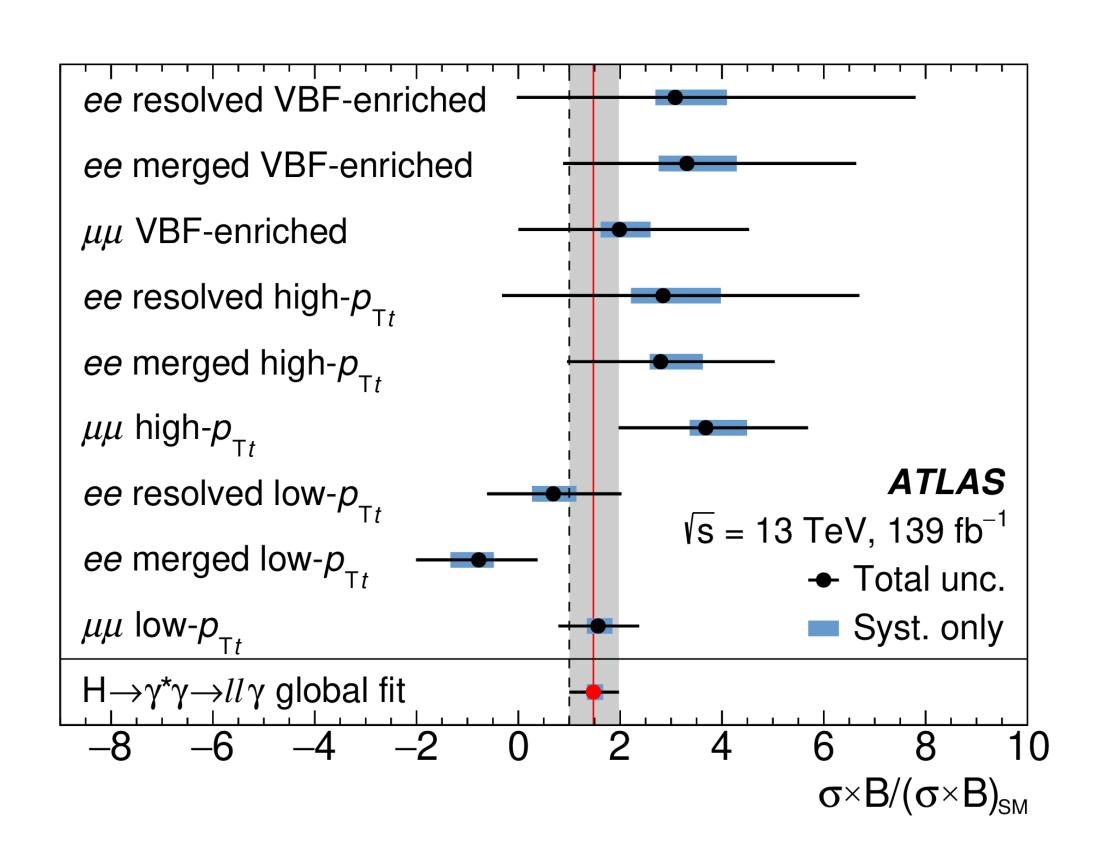

Six (out of nine) signal regions are shown below

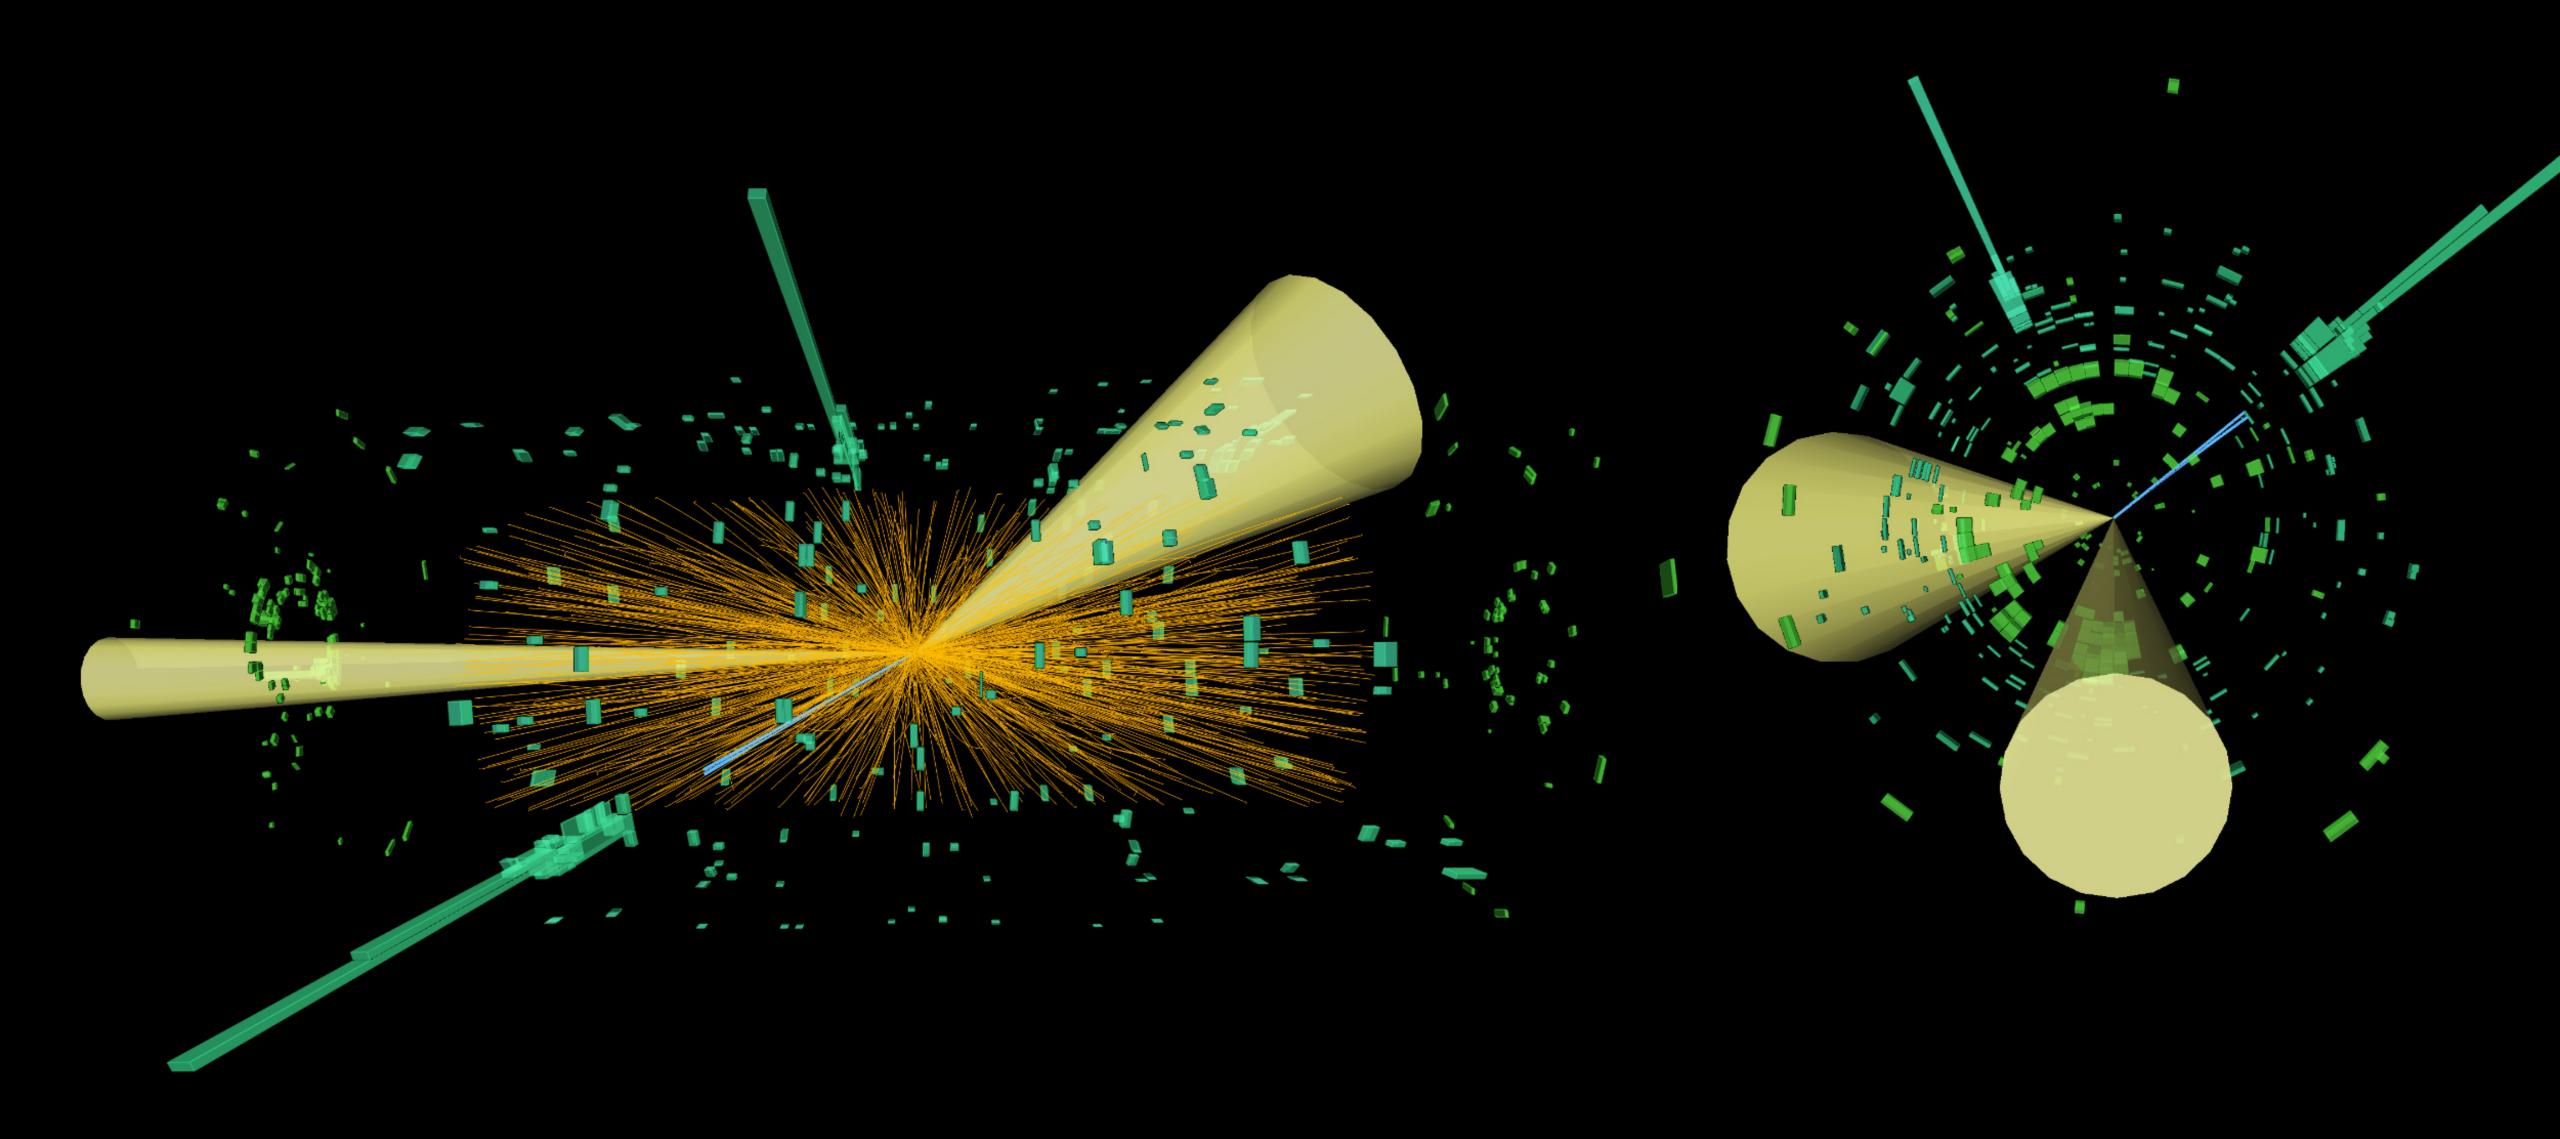

Results

- Measured fiducial $\sigma(pp \rightarrow H) \times B(H \rightarrow ll\gamma)$ (m_{||} < 30 GeV): 8.7 ± 2.8 fb
 - Corresponds to the signal strength $\mu = 1.5 \pm 0.5$
 - Analysis is statistically-dominated, leading systematic uncertainty: background modeling
- Significance above background-only hypothesis: 3.2σ
 - First evidence for H→IIγ decay!

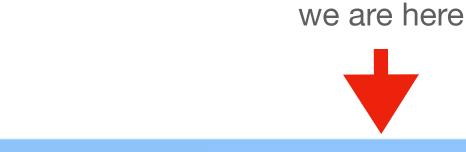

Search for H→IIy decays at low-mil

The High-Luminosity LHC

- 20 times more integrated luminosity than LHC Run 2
 - Up to 200 pp interactions per bunch crossing!
- Better detectors, larger acceptance, better triggers
- Improved theory and analysis methods

Prospects at High-Luminosity LHC (3000 fb⁻¹)

 Good potential for discovery of H→Zγ (and H→γ*γ) decays

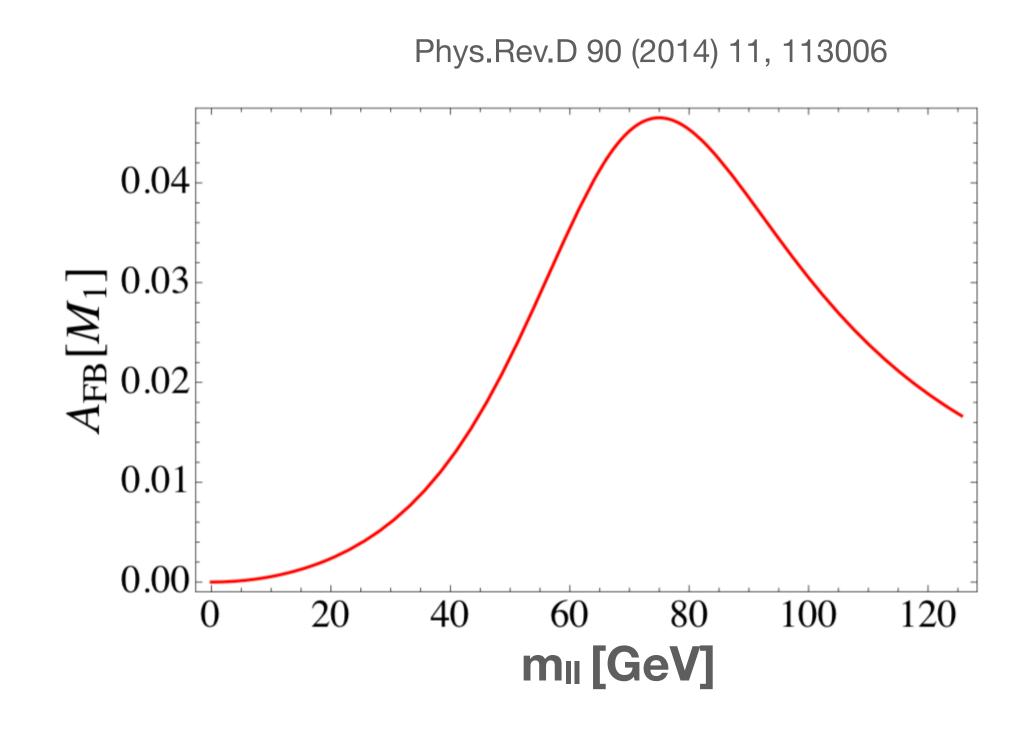

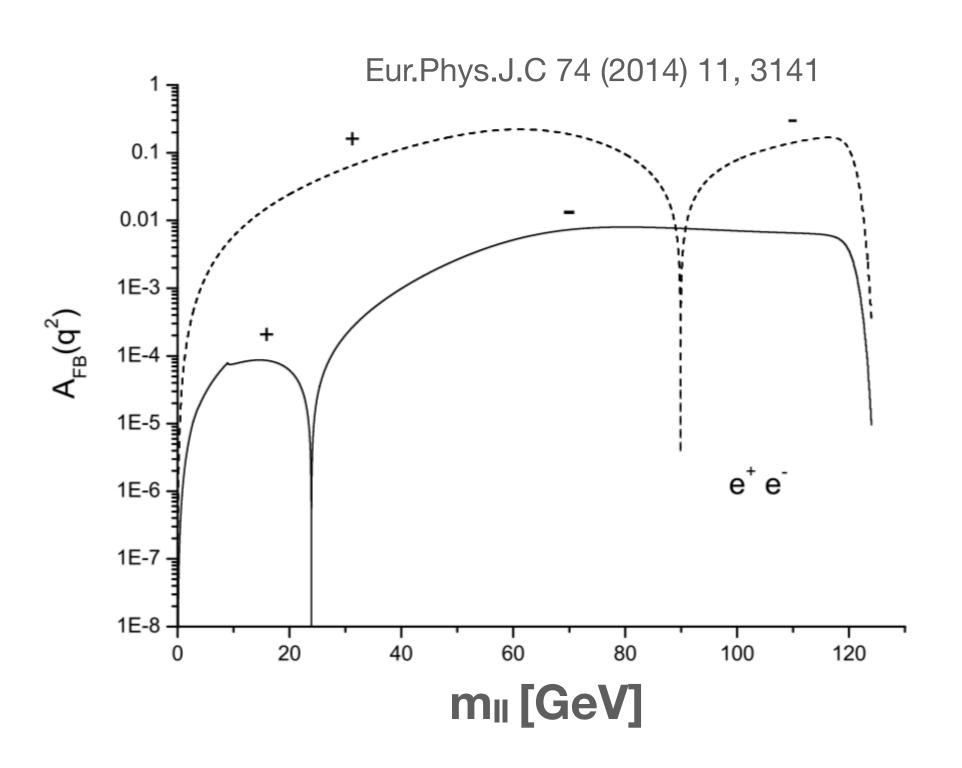

arXiv:1902.00134

Prospects at High-Luminosity LHC (3000 fb⁻¹)

- With three-body H→IIγ decay, it is possible to probe CP-violating Higgs couplings
 - Lepton forward-backward asymmetry measurements (note $A_{FB}(q^2) = 0$ for SM Higgs boson)
 - More detailed access to loops, exotic couplings, ...

$$A_{\mathrm{FB}} = \frac{\sigma_{\mathrm{F}} - \sigma_{\mathrm{B}}}{\sigma_{\mathrm{F}} + \sigma_{\mathrm{B}}}$$

Summary

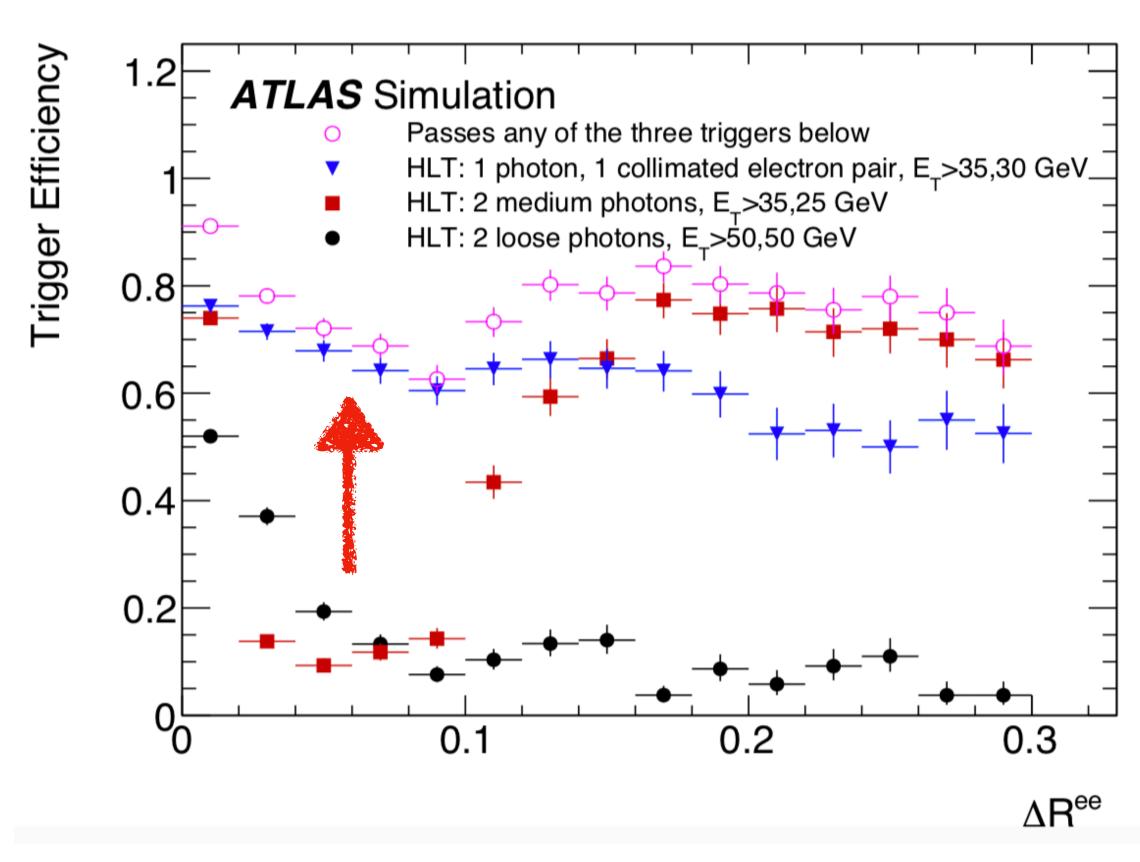

- ATLAS experiment continues to probe the nature of the Higgs boson using full LHC Run 2 pp data at 13 TeV (~140 fb⁻¹)
- Evidence for H→IIγ decay at low-m_{II}
 - 3.2 σ , μ =1.5 ±0.5
 - One of the rarest Higgs boson decays with **B=10**-4
- ~5% of the LHC integrated luminosity has been achieved so far
 - HL-LHC will be able to probe more precisely rare Higgs boson decays

Backup

Trigger

- Can't rely on regular single-lepton triggers alone
 - Combination of single-lepton, 2I, γ+I, γγ, γ+2I triggers is used
 - Dedicated merged-ee + γ trigger is also employed
- Trigger efficiency wrt final selection:
 - Muon channels: 96.2%
 - Resolved electron categories: 96.5%
 - Merged electron categories: 99.8%

Eur. Phys. J. C 80 (2020) 47

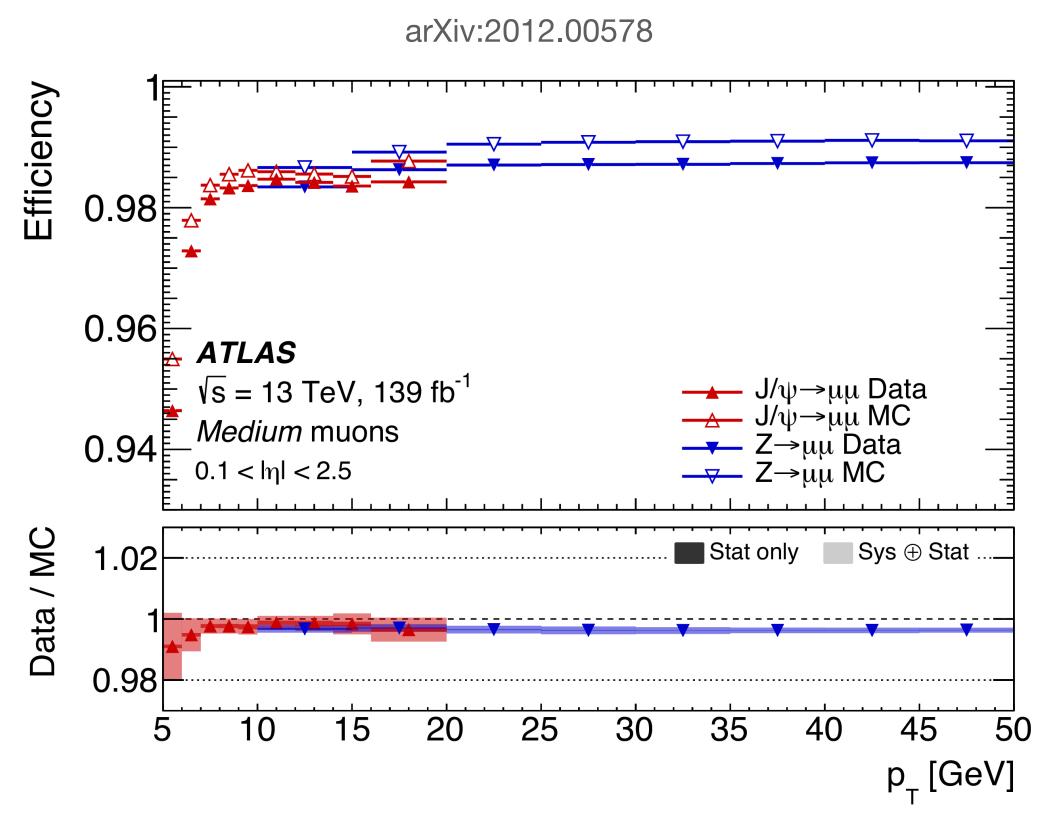

Systematic uncertainties

Relative systematic uncertainties (in per cent) in the measured signal strength and the measured cross-section times branching ratio

Total	33		32

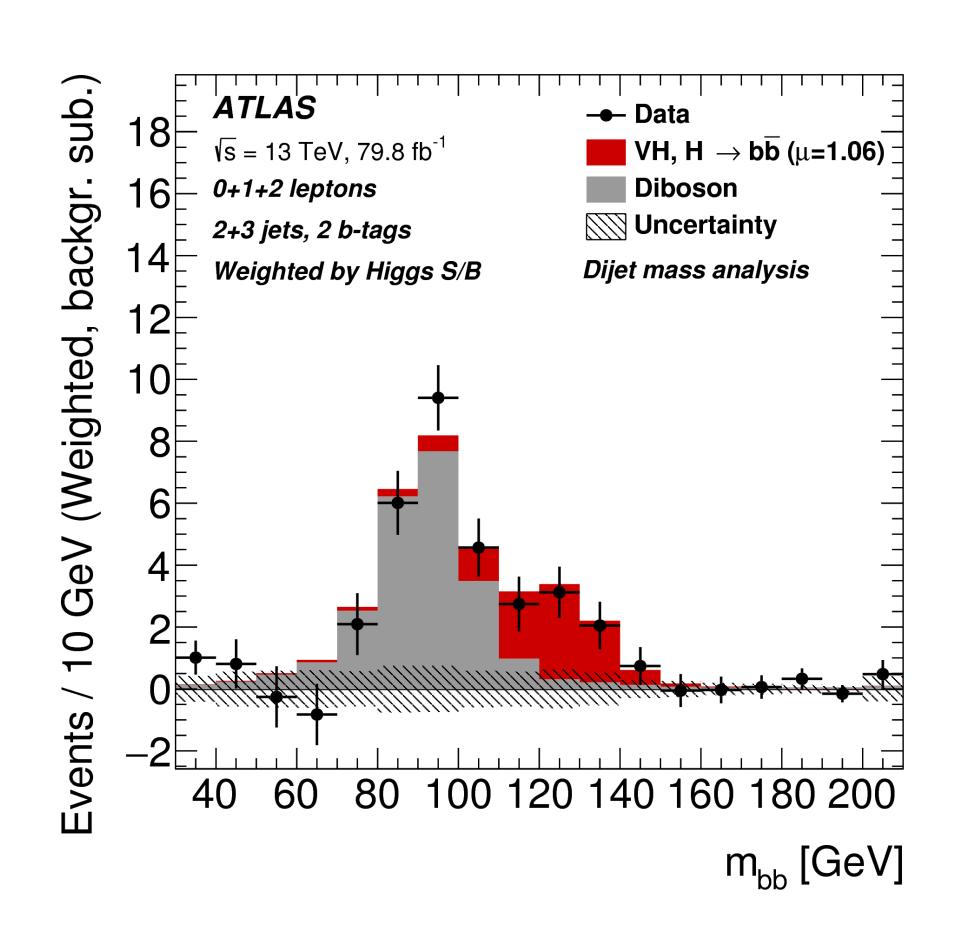

ATLAS detector performance

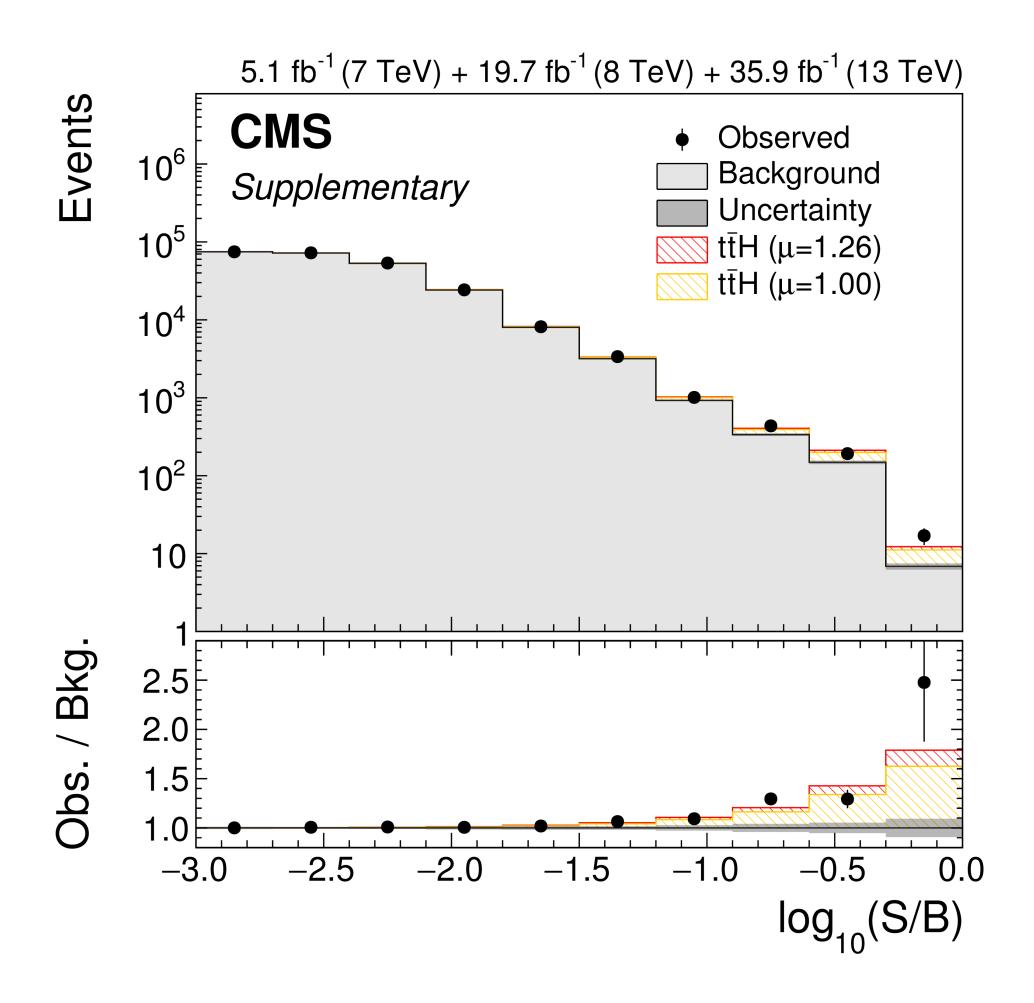

- Good understanding of the detector is critical
- Reconstruction of physics objects (e, γ, μ, τ, jets, ...) precisely known from careful data-driven calibrations
- Several improvements during the last years using machine learning techniques

What do we know about the Higgs boson after LHC Run 2?

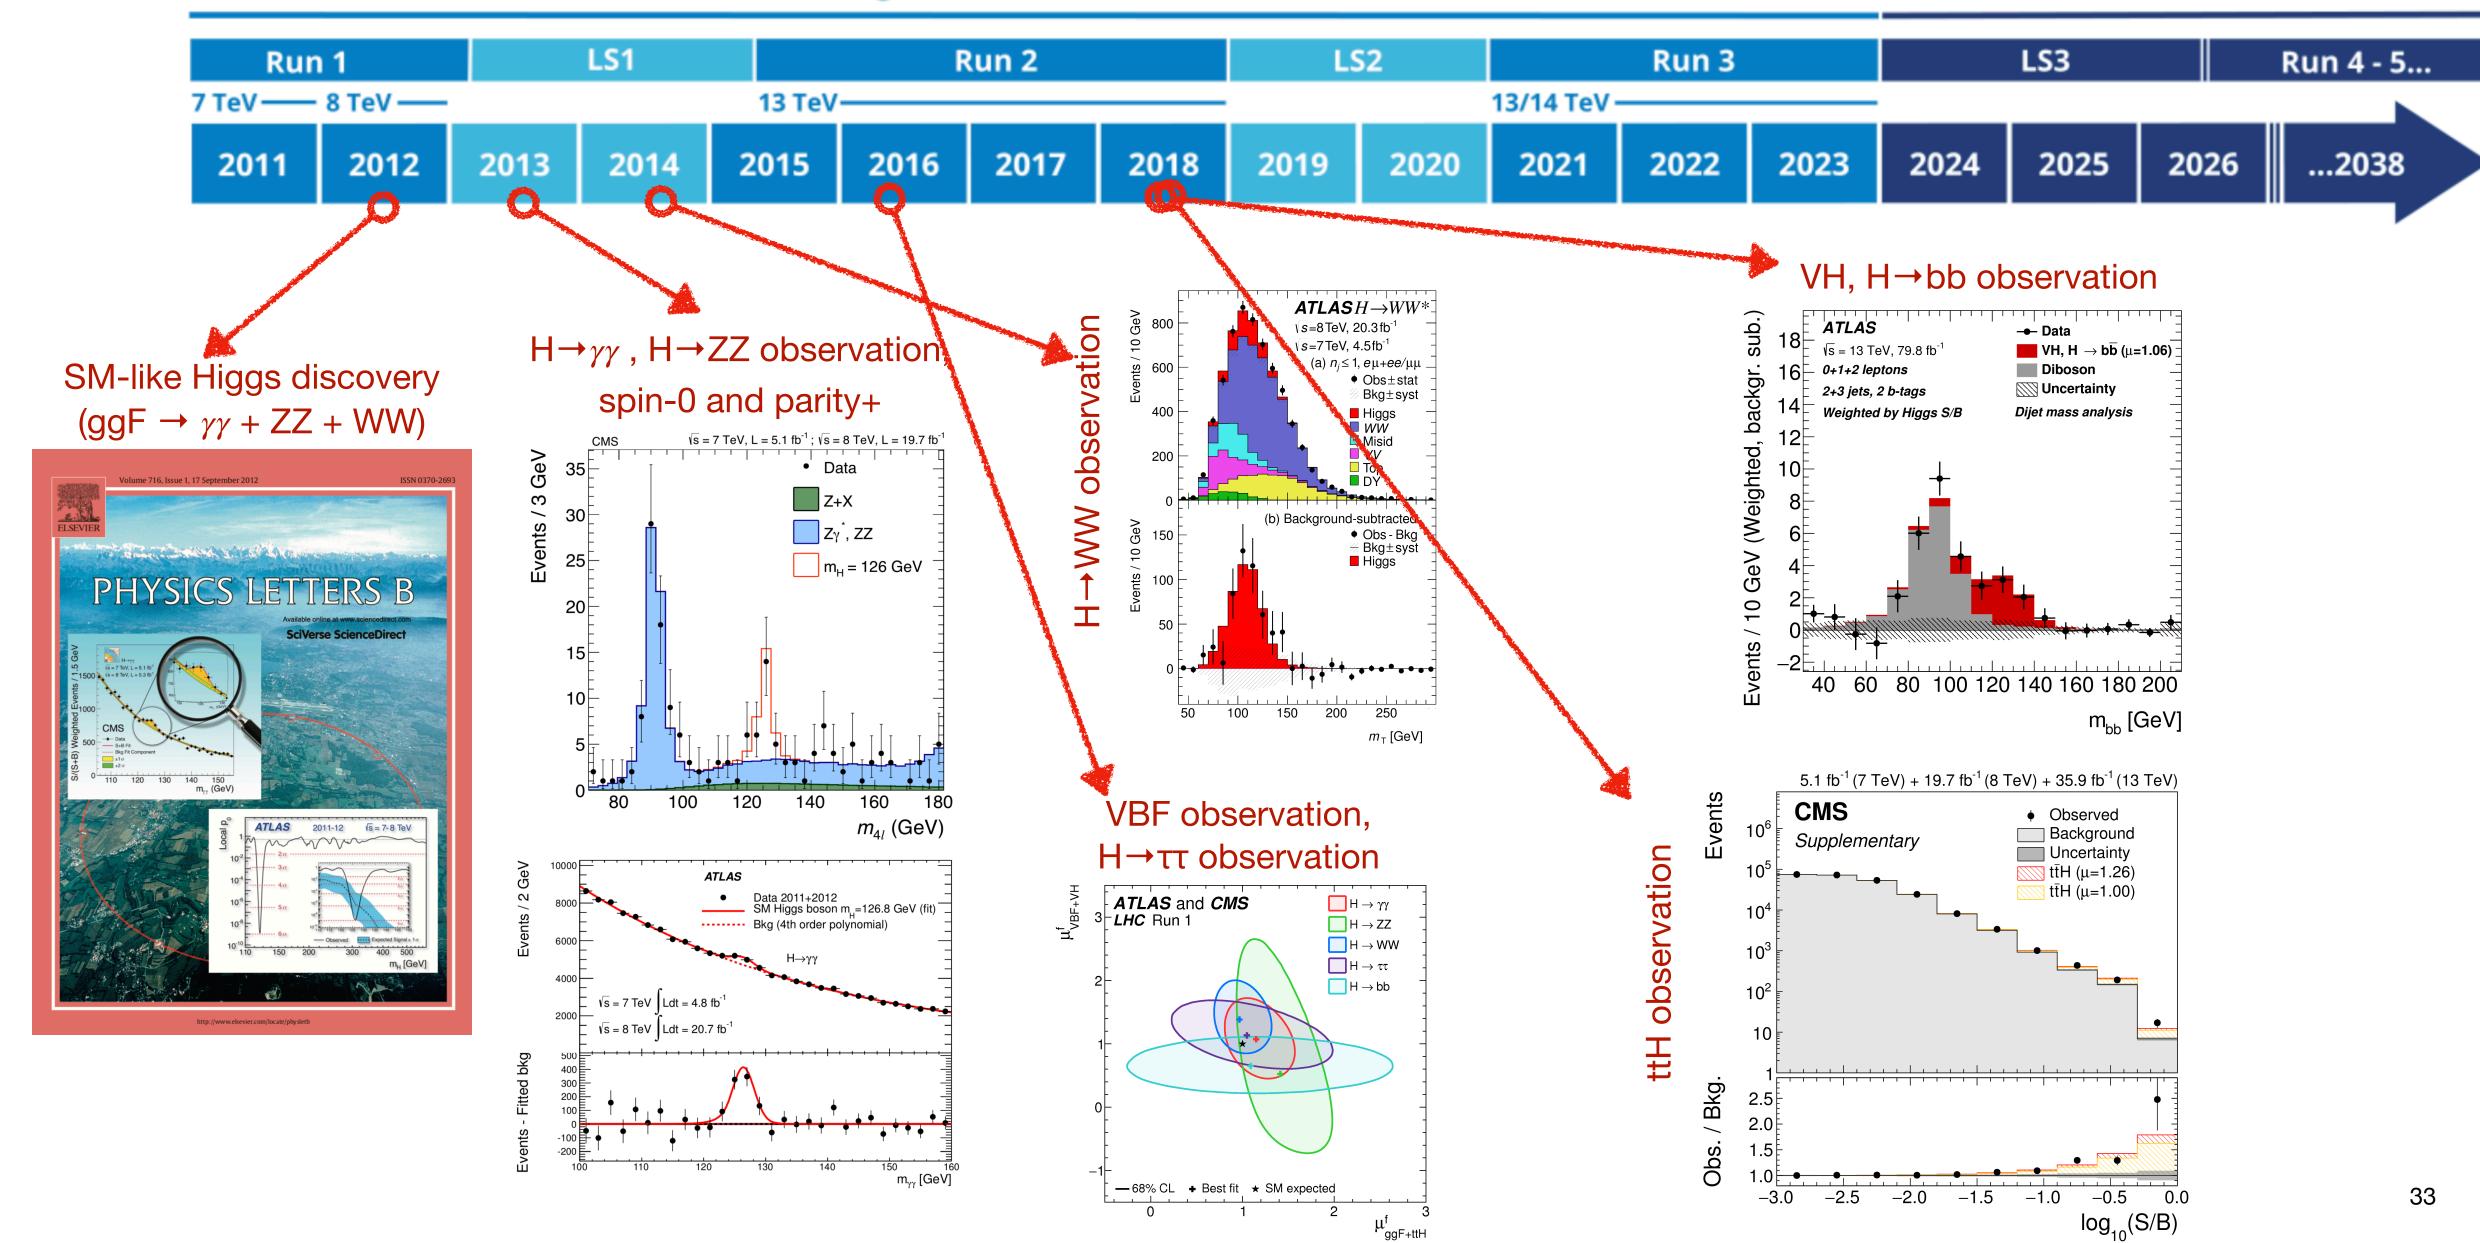

Fermionic couplings confirmed: observation of H→bb decay and ttH process

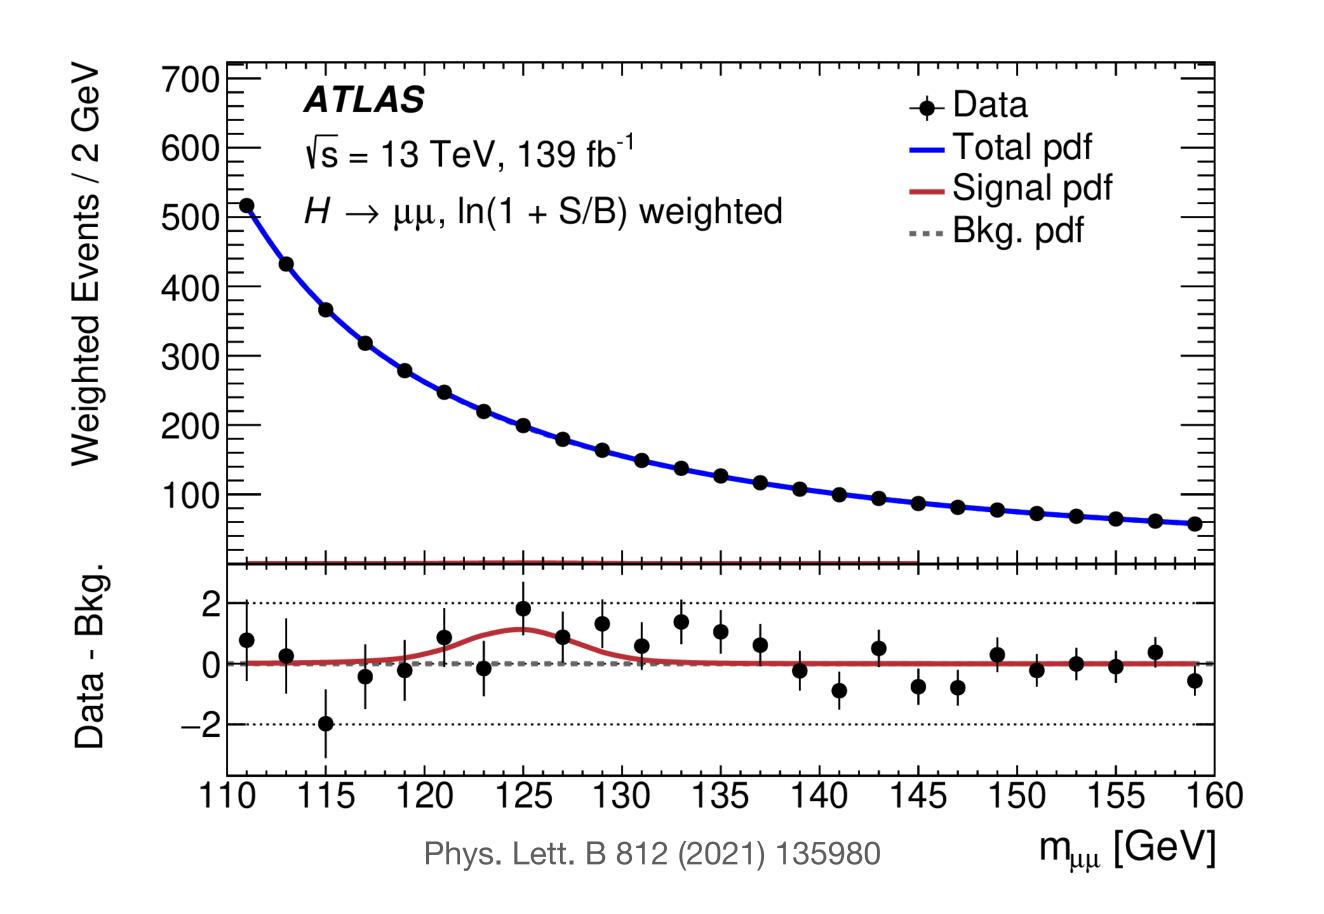

Higgs boson observation timeline at the LHC

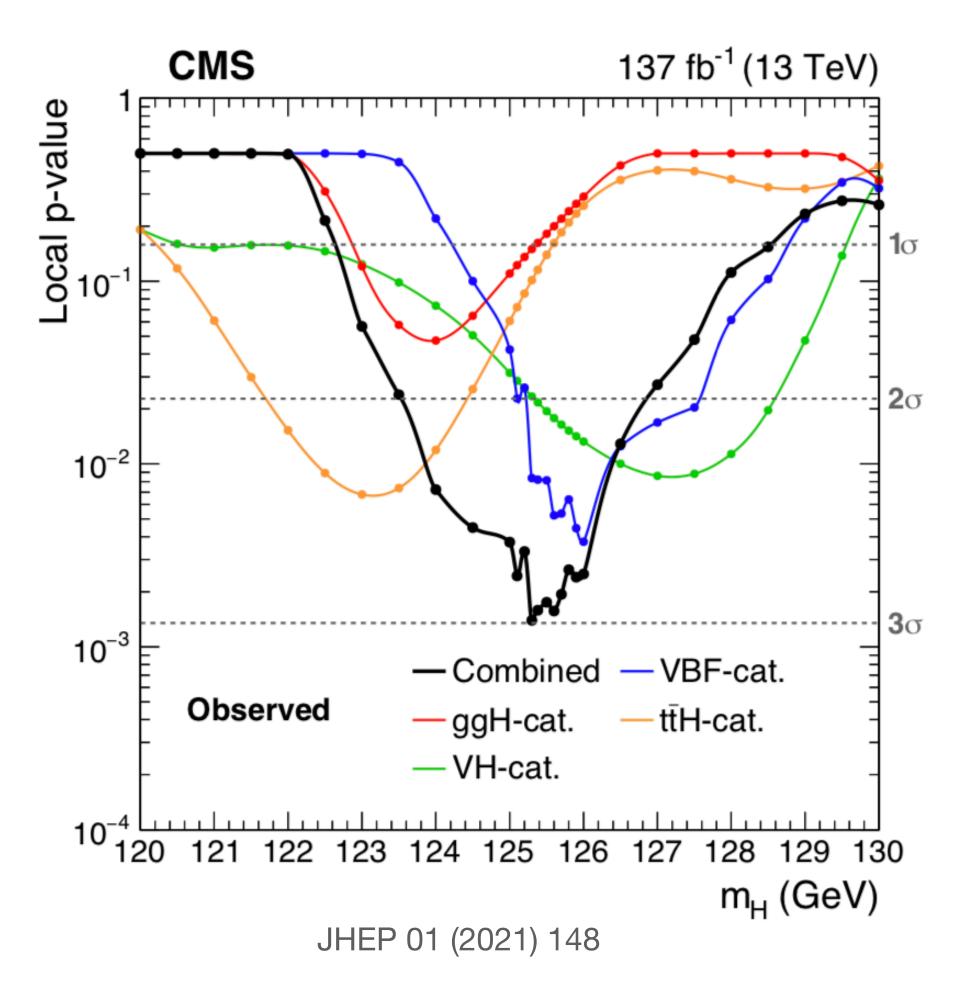

Large Hadron Collider (LHC) HL-LHC

What do we know about the Higgs boson after LHC Run 2?

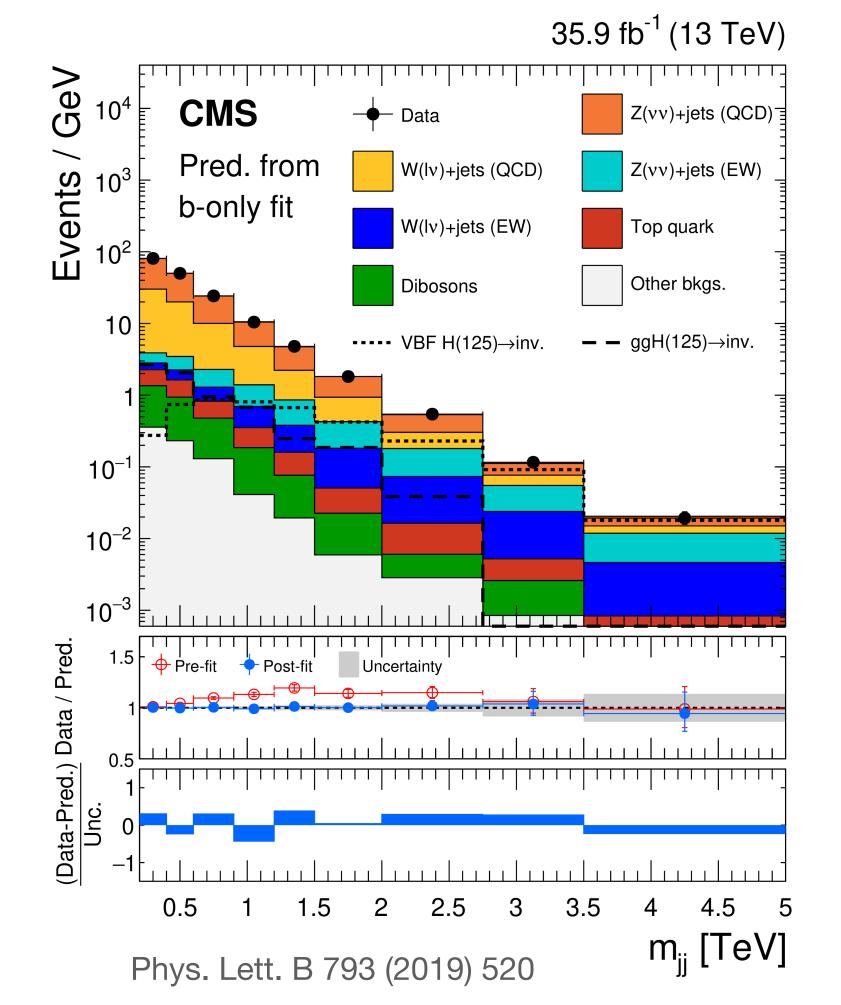

- LHC data gives access to very rare Higgs decays: $B(H \rightarrow \mu\mu) = 2.2 \times 10^{-4}$
- Evidence for H→µµ decay
 - ATLAS: 2.0σ (1.7 σ) obs. (exp.) significance, $\mu = 1.2 \pm 0.6$
 - CMS: 3.0σ (2.5 σ) obs. (exp.), $\mu = 1.2 \pm 0.4$

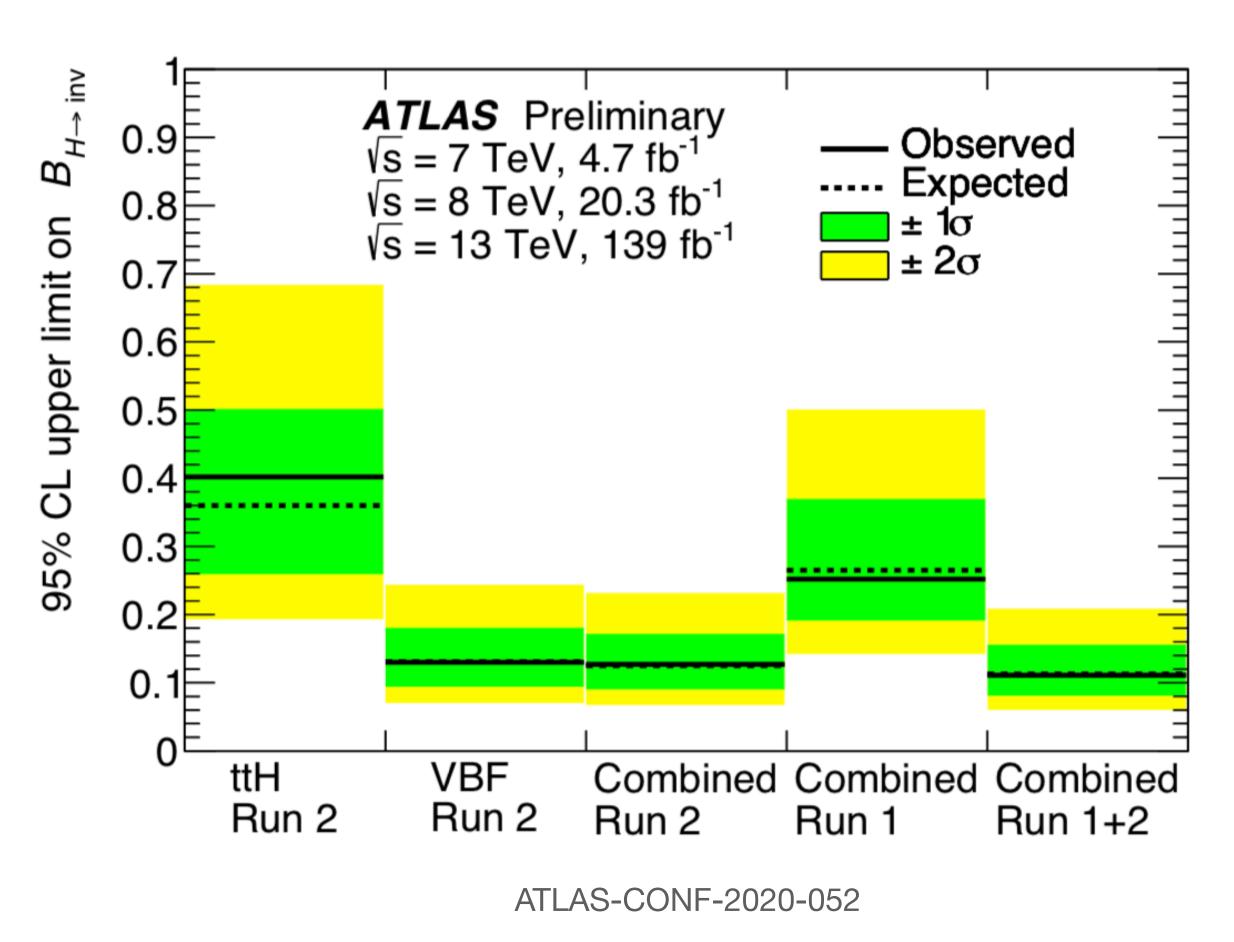

What do we know about the Higgs boson after LHC Run 2?

- Searches for Higgs to invisible have been performed in VBF, ttH and VH channels in both ATLAS and CMS
 - Observed upper limit $B(H \rightarrow inv.) = 0.11$ (95% CL) from recent ATLAS combination

Higgs coupling measurements - the kappa framework

- Parameterisations of Higgs boson production cross-sections and decay widths as a function of coupling strength modifiers using kappa framework
- Considering leading order contributions only
 - Other assumptions are typically made

$$\kappa_j^2 = \frac{\sigma_j}{\sigma_j^{\text{SM}}} \quad \text{or} \quad \kappa_j^2 = \frac{\Gamma_j}{\Gamma_j^{\text{SM}}}$$

Constraints on Higgs boson width

- Indirect measurement from off-shell production in H→ZZ channel
- Obs. limit on Higgs width:

 $\sigma_{\mathrm{vv} \to \mathrm{H} \to 4\ell}^{\mathrm{on\text{-}shell}} \propto \mu_{\mathrm{vv}}$ and $\sigma_{\mathrm{vv} \to \mathrm{H} \to 4\ell}^{\mathrm{off\text{-}shell}} \propto \mu_{\mathrm{vv}} \Gamma_{\mathrm{H}}$

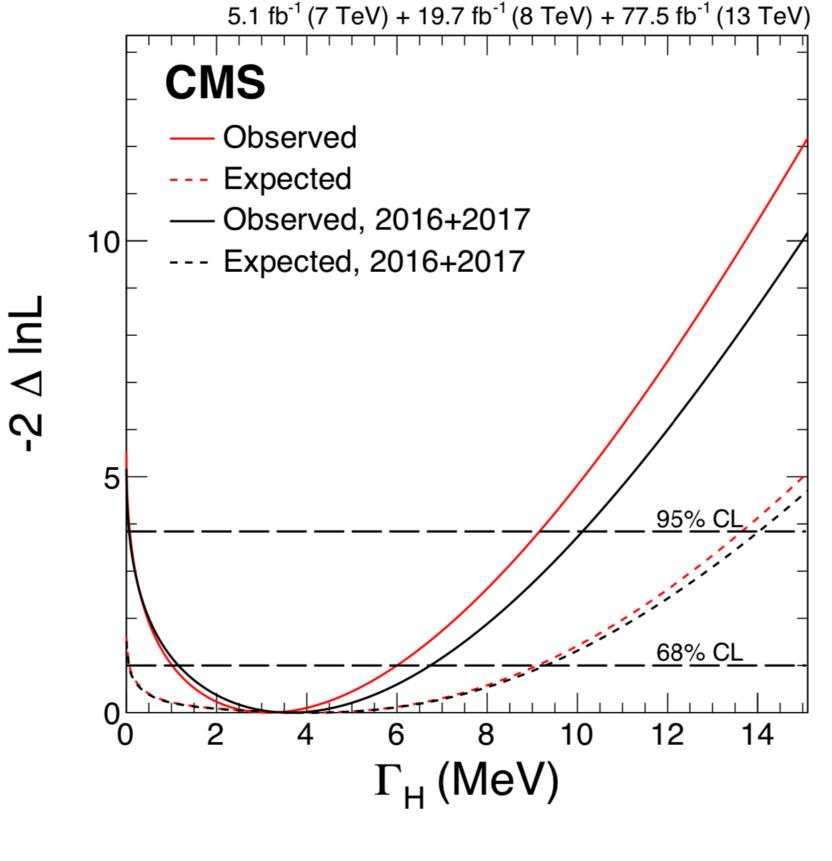

- ATLAS Run 2 (36.1fb⁻¹): < **14.4 MeV**
- CMS Run 1+2 (77 fb⁻¹): [0.08, 9.16] MeV
- SM prediction: 4.1 MeV

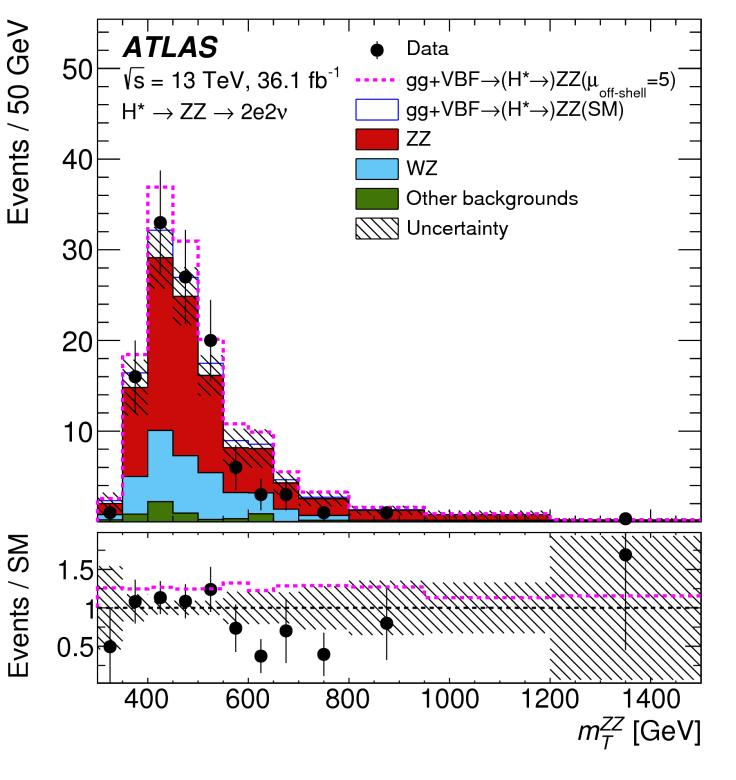

HL-LHC projections:

CMS: $4.1^{+1.0}_{-1.1}$ MeV

ATLAS: $4.2^{+1.5}_{-2.1} \text{ MeV}$
